(That this method of procedure is not necessary or superior to others in the treatment of the well-to-do classes is granted by the writers, at the start; and the element of danger that they concede at the close, while slight, should be taken into careful account. It is admitted by almost all observers that ringworm of the scalp varies greatly in its frequency, and also in its response to treatment in different localities. In New England, as illustrated by the patients who apply for treatment in Boston, this malady, among the better classes, does not belong in the category of the more obstinate skin affections. Careful attention to the hygiene of the whole scalp and head is most important during local treatment of areas of ringworm,—a point that has not been sufficiently emphasized. Daily soap washings and mild borated and antiseptic lotions should be ordered for the whole head. Epilation and the application of parasiticides to the affected areas, in addition to this, will bring about a cure in from three to four months in almost all cases when the treatment is rigorously followed, and care taken to prevent reinfection from any source. This is a period no longer than that claimed for the treatment by intensive x-ray exposure, and the method is wholly devoid of danger. The intensive x-ray treatment of ringworm in the vicinity of Boston should be limited to hospital practice among people who are unable or unwilling to carry out other methods systematically, and should always be confined to the hands of experienced radiologists. Reporter.)

#### TRICHLOROACETIC ACID IN DERMATOLOGY.<sup>3</sup>

A paper was read, at the 39th annual meeting of the American Dermatological Society, on the uses of trichloroacetic acid in dermatology, by Dr. Charles N. Davis of Philadelphia. Dr. Davis was led to the use of this acid by the fact, pointed out to him by a laryngologist, that it caused a dry eschar when used as a cauterant on the mucous membrane of the mouth. Hence he concluded that a dry eschar on the skin would be of advantage in preventing the invasion of micro-organisms. He first used it with good results on patches of degenerative seborrhea and on pigmented moles. His method of procedure is to cleanse first the surface of the skin with benzine, to remove the oil, then to clean further with an alcohol pad. Then a saturated solution of the acid is applied to the area to be operated on with a piece of cotton twisted on a Japanese bamboo toothpick until the surface is white. Then a pad of cotton wet with water is applied to cause the acid to act more thoroughly on the tissues. Then the acid is neutralized with an alkaline solution, usually a 4 or 5% Labarraque solution. The cauterized area is then covered with an ichthyol varnish, 25% of ichthyol in a saturated solution of bor-

acetic acid, to which eight grains of tragacanth to the ounce is added. A small bit of teased-out cotton is then inserted, which in turn is painted with the ichthyol varnish. Usually there is no secondary infection, and the original dressing may be left on until the wound heals over.

This method of treatment has been found most efficient in pigmentations, papillomata, and naevi. In soft and flat warts, and in verruca senilis, the treatment with the acid is best preceded by the application of salicylic acid plaster to the area, this salicylic acid plaster to be covered in with a larger piece of ichthyol plaster, worn if possible for five or six days. Davis thinks that this is the ideal form of treatment in xanthoma palpebrarum. One painting is usually sufficient. The eyelid is put on the stretch to widen the patch, and to make sure that the edge is cauterized. It is afterward to be carefully dressed with the ichthyol varnish, without embedding the bit of cotton. The scar that follows is slightly depressed, but the eyelid folds back normally. Its action is excellent, also, in the so-called spider cancer, forming a thrombus. In the small, elevated, compressible naevi in children, Davis prefers the acid to carbon dioxide snow, as it is easy of application, causes little pain, and is not followed by inflammatory lesions. It is also very satisfactory in molluscum contagiosum. Usually one painting causes them to dry up and fall off in a few days. The small fibromata of the chest and neck are also treated in this way. He has had good results also in lupus erythematosus and in acne varioliformis. In beginning rodent ulcer and in small superficial epithelioma of the face, especially in the timid who refuse a radical excision, or in cases in which it seems wise not to reveal the nature of the trouble, Davis recommends removing the crusts, wearing a salicylic-diachylon ointment for a few days and then dusting powdered cocaine on the raw surface. This causes anesthesia to eurenting, after which cocaine is again dusted on, and the base cauterized for a sixteenth to an eighth of an inch outside of the border, and the wound then covered with ichthyol varnish. This he finds much more satisfactory than the old method of caustic potash and pyrogallol. Oftentimes these will heal without having to remove the original fixed ichthyol varnish dressing. Benign cystic epitheliomata have also been treated in this way. It has been found valuable also in fissures about the mucous orifices and in milium.

#### NEW AND OLD METHODS OF TREATMENT.

MacKee<sup>1</sup> read a very logical and sane paper to the Section of Pediatrics of the New York Academy of Medicine on January 13, 1916, on the subject of the modern treatment of skin diseases. He refers to the recent tendency to search for the causes of cutaneous disturbances in the internal secretions, gastro-intestinal troubles, fecal infection, etc., as marking a hopeful

outlook, although very little has as yet been added in the shape of practical results. He considers that research has added much to our knowledge of eczema. Sabouraud and Whitfield have shown that the so-called eczema between the toes and fingers, and also eczema marginatum of the groin and thighs, is of parasitic origin. Other researchers have thrown some light on the catarrhs of the skin following a local pyogenic infection, and on many occupational disorders.

In specific lines of therapeutics of the skin progress has not been very remarkable during the last year or two. MacKee speaks cautiously of vaccine therapeutics. He seems hopeful of the future of vaccine treatment of ringworm of the scalp, a method now under trial, but of which it is too early to predict results. The former successes reported from the vaccine treatment of acne vulgaris have not been substantiated. Polyvalent stock mixtures of the staphylococcus, if properly used, are of distinct value in pustular acne, but will not produce a cure unless combined with other methods. He thinks tuberculin treatment is specific for erythema induratum. The Kromayer lamp, which produces actinic and ultra violet rays, has been found at Fordyce's clinic in New York to be efficacious in many cases of acne vulgaris and alopecia areata, as well as in certain types of psoriasis, eczema, and lichen planus. In more serious and obstinate cases, such as lupus and naevi, when the ultra violet rays alone are indicated, MacKee has had no success with it.

With regard to radium, MacKee thinks that there is a decided misunderstanding as to the comparative value of this agent and of the x-rays. Radium has given excellent results in the treatment of deep-seated vascular naevi, but is not so effective in port-wine mark. It is superior to x-ray in leucoplakia and lupus erythematosus, and in inaccessible locations. The x-ray is indicated where extensive surfaces are to be treated.

With regard to auto-serum, his conclusions are that although it may have some results in the treatment of psoriasis, urticaria, and certain vesicular and bullous affections, its results do not, on the whole, warrant the time, trouble, and expense.

Refrigeration, by carbon dioxide snow, is considered to have stood the test of time, and to be one of our most valuable agents in the treatment of lupus erythematosus and of some naevi. It should never be used in the treatment of epithelioma.

MacKee rightly calls attention to the fact that we often lose sight of the value of the older methods of treatment. Trimble has recently reported cases of lupus erythematosus successfully treated by some of the older methods, such as quinine and the tincture of iodine. Davis has shown the superiority of trichloroacetic acid in certain affections, and the fact that keloid follows the use of this substance less frequently

than that of any other chemical caustic; and Sherwell has cured epitheliomata with acid nitrate of mercury where both x-ray and surgery have failed.

The best hope of progress lies in the combined efforts of the dermatologist and the internist, aided by the physiological chemist, the bacteriologist and the pathologist.

#### SCLERODERMA WITH DISEASE OF THE THYROID.<sup>3</sup>

Sequeira, of London, describes four cases of scleroderma associated with thyroid disease. In three of these cases Graves' disease was present, in one the scleroderma developed in a myxoedematous patient who was taking thyroid. These four cases were part of a series of twenty-two seen by the writer during recent years. The first case concerned a single woman of 22, who presented a sclerodermatous condition of the lower half of the left leg, the duration of which is not stated. Over this area an ulcer had developed secondarily, from an injury. There was also a small area of scleroderma on the inner side of the right leg. The thyroid gland was enlarged and prominent and there was marked tachycardia. The ulcer was gradually healed by means of stimulating applications. Two courses of thyroid extract, as has been recommended, had no effect on the scleroderma, or on the ulcer, and it seemed as if the general condition was made worse. X-ray applied to the enlarged thyroid had a definite effect on the general condition and may have contributed to the healing of the ulcer, but had no appreciable effect on the scleroderma.

The second case was also a woman of 22, who presented several areas of scleroderma in the chest and over the scapulae as well as on the hips. The patient was anemic, suffered from frequent headaches, had a quick pulse, protrusion of the eyeballs and an enlargement of the thyroid gland. The third case developed in a woman of 59, who showed patches of scleroderma on each leg, with tachycardia, proptosis, and protrusion of the thyroid gland. The fourth case was that of a woman of 42, who had had a scleroderma of both lower legs for about a year. She had been under treatment for myxoedema with thyroid extract for fifteen years. She showed a remarkable sensitiveness to the drug, which had kept the myxoedema under control.

Discussing the pathogenesis of this affection, Sequeira observes that it occurs in connection with such a variety of conditions that it is hard to believe that many of the causal relationships that have been claimed for it have a sure foundation. Theories of a lymphatic, infectious, and tropho-neurotic origin have been advanced in turn, the last named being the one that has been most popular. It has also been claimed to be the result of extensive endarteritis, and has occasionally been associated with Raynaud's disease. Its possible relationship, in some cases at least, with syphilis has been advanced, and posi-

tive Wassermann reactions have been recorded by a number of observers. The coexistence of scleroderma and affections of the thyroid has been noted by many writers. According to Roques, thyroid atrophy seems to be more common than hypertrophy. Yet Dittisheim found eight cases of scleroderma in seventeen cases of exophthalmic goitre. Treatment by means of the thyroid gland has not proved very satisfactory. Roques collected 67 cases in which this treatment had been employed, with the result of a cure in four, an improvement in 32, and no effect in 31. Sequeira agrees with Osler that thyroid extract has no specific action in scleroderma as it has in myxoedema. He could not find that the skin in any case became softened or regained its normal consistency. Addison's disease has sometimes been reported as coexisting with scleroderma, but Osler's caution that hyperpigmentation is very common in scleroderma should be emphasized.

The writer's own conclusions are that lymphatic obstruction as a cause may be excluded. The localized band variety may probably be considered with propriety a tropho-neurosis. While it is true that a certain proportion of the cases are associated with affections of the thyroid gland, there is nothing to warrant the assertion that alterations in the activity of the gland or of its secretions are actually the cause of the affection. The fact that both atrophy and hypertrophy of the thyroid accompany this condition makes one cautious in forming conclusions.

It is impossible to exclude changes in the character of the secretion.

### Society Report.

#### THE NEW ENGLAND SOCIETY OF DERMATOLOGY AND SYPHILIS.

The third meeting of the Society was held at the Massachusetts General Hospital on January 27, 1916, with the president, Dr. Abner Post, in the chair.

The following cases were presented:

##### I. BRUCCINOMYCOSIS.

Presented by Dr. C. J. WHITE.

Twenty-six years ago, a man, now sixty-four years of age, was sick in bed with fever, rash and sore throat for about five weeks. During this illness he first noticed a small "pimple" upon the dorsum of the left hand appearing in the scar of an extensive burn, which he had received two years previously. This lesion gradually enlarged and formed a shallow

ulcer. At the outset a similar lesion appeared just beneath the right lower eyelid which has enlarged and remained in a more or less active condition ever since. There was also a painful lesion on the left instep which healed, leaving a deep scar. The lesion on the left arm showed but little tendency to increase in size until two years ago, but since that time there has been a progressive enlargement of the original ulcer and several new ones have appeared both upon the arm and upon the fingers of the left hand. The patient states that the ulcers have always tended to heal centrally and extend peripherally. For many years the patient has taken large doses of KI., even up to gr. 480 a week.

Today, the man presents at the outer canthus of his right eye, involving both lids, a roughly symmetrical lesion, the size of a twenty-five cent piece, with sharp borders and red granulating base. On the left forearm, just above the wrist, is an irregular ulcer about the size of the palm of the hand, with dirty granulations and irregular bluish edges. Above this area are two dime-sized lesions with heaped-up, pearly crusts. Covering almost the entire left forearm is the scar of the burn received twenty-eight years ago. There is a small, irregular scar upon the left instep the size of a dime.

With applications of fuchsin ointment the ulcer upon the arm showed every indication of rapid healing. Ten days after admission fuchsin ointment being no longer available, balsam of Peru was substituted. Tissue was removed for diagnosis and under the microscope presented a typical picture of blastomycosis. Several smears of pus secured from the lesions since that time have contained numerous budding organisms.

## 2. NAEVUS VASCULARIS TREATED BY THE KROMAYER LAMP.

Presented by DR. E. L. OLIVER.

The patient was a young woman with a "port wine" mark covering a large portion of her right cheek. Various men had tried divers means of destruction, including CO<sub>2</sub> snow and radium. The artificial snow had proved ineffectual, while radium had diminished the color somewhat, but was proving a very slow method owing to the small available supply of the metal. Several exposures to the Kromayer lamp have produced results decidedly superior to those gained by previous methods, both in the bleaching of the color and in the size of the areas treated.

## 3. DERMATITIS HERPETIFORMIS.

Presented by DR. C. J. WHITE.

In January, 1915, an eruption of small vesicles appeared upon the right arm of a woman, age thirty-eight. At this time the patient was in poor general condition and consulted her local physician, who prescribed for anemia a medicine containing KI. gr. 15 t.i.d. Within a few hours after the ingestion of the first dose of this medicine, the lymph nodes of both sides of the neck became swollen and painful. This glandular reaction was followed at once by a diffuse vesicular eruption distributed over the region about the lower jaw, neck, and upper chest. During a period of two weeks following, the process spread in segmental crops of vesicles down the trunk and extremities, each crop lasting two or three days. The patient remained in bed during this period. Itching was persistent.

Treatment consisted of the application of a sulphur ointment together with the medicine mentioned above. In June a second eruption similar to the first appeared upon the trunk, but was mild in nature and persisted only a few days. From that time until the present attack, small groups of vesicles have been present somewhere on the body. About Thanksgiving time many new lesions appeared and the patient resumed the use of the medicine prescribed in January. Following this, a rapidly spreading generalized vesicular eruption broke out, and from that time until entrance to the hospital, Dec. 27, 1915, many new crops of vesicles have continued to appear.

The skin generally, with the exception of the face and abdomen, is covered with a papular eruption and shows many punctate and linear excoriations. The papules are discrete and confluent, many with umbilicated tops covered with thin sero-hemorrhagic crusts. Many of the lesions are arranged in a more or less crescentic manner. There are many shiny, erythematous areas resulting from former lesions. Moderate enlargement of the lymph nodes of both groins is present. The Wassermann test is negative.

During the patient's stay in the ward, many small groups of vesicles have appeared from time to time. The treatment has consisted of a non-acid diet, Fowler's solution and the local applications of a sulphur-zinc oxide-lard ointment.

## 4. DECEPTIVE TINEA TRICOPHYTINA (MICROSPORON AUDOUIN).

Presented by DR. F. S. BURNS.

Duration one year (?). Over the mid-occipital region, a little to the left of the median line, there is a rounded area, two inches in diameter, consisting of a good deal of dry, coarse, furfuraceous scaling, without apparent alopecia, and without any cutaneous alteration. Hairs removed from this area reveal profusion of small spores.

## 5. INHERITED SYPHILIS.

Presented by DR. C. MORTON SMITH.

The mother of the patient has a strongly positive Wassermann reaction, but no clinical signs of lues. Her infection occurred probably seven or eight years ago, as she had a stillbirth with macerated fetus at that time.

The patient was born at full term, apparently healthy, and is now six weeks old. Marked snuffles developed soon after birth and have persisted. A general syphilide appeared within a few days, maculo-papular in type, with vesicles and small bullae in the palms and soles. The child is poorly developed and nourished, and has thin hair over the temples and prominent veins. There are transverse fissures of the lips and cracks at the corners of the mouth. There is a general glandular enlargement, a purulent conjunctivitis and profuse nasal discharge, making breathing difficult at times. There are also mucous lesions about the anus.

## 6. LARGE-SPORED RINGWORM.

Presented by DR. C. J. WHITE.

The present eruption began one month ago, when there was noticed a discrete, circular lesion about the size of a twenty-five cent piece, showing a tendency toward scaling, which in a few days changed to a thick yellow crust. The patient applied iodine, but

the lesion steadily became larger in circumference and markedly raised above the level of skin surface. Ten days ago the man was seen by a local physician, who advised the daily cleansing of the lesion with H<sub>2</sub>O, and the application of a paste. There is no history of similar condition among his associates and no ringworm has been observed upon his cattle.

Physical examination is negative except for the local condition of the skin beneath the jaw, where there is a lesion three by five cm. raised about 1/2 cm. above the level of the skin, reddened, infiltrated and showing loss of most of the hairs of the beard and numerous infected follicles from which pus can be expressed. There is no reaction in the surrounding skin. Beneath the left jaw are two smaller lesions of a similar character. Under the microscope pus expressed from largest lesion shows many spores compatible with the megalosporon ectothrix ringworm.

#### 7. TUBERCULOSIS CUTIS WITH TUBERCULOSIS OF THE LARYNX.

Presented by Dr. J. H. BLAISDELL.

A man, perhaps twenty-eight years of age, decidedly aphonic from tuberculosis of the larynx, asserts that the present condition of the skin has existed for two years. Today, over the metacarpophalangeal joint of the left forefinger is a circular area, the distal half of which is surrounded by a markedly elevated purple wall, which is not papular but uneven, merely an exaggeration of the central structure. The skin is infiltrated, dry, and cracking. The microscopical examination reveals the tuberculous structure of the lesion.

There is also practically complete obliteration of the opening from the naso-pharynx to the throat, apparently due to late destructive ulcerations and the formation of extensive scar tissue. The Wassermann test is strongly positive.

#### 8. LICHEN PLANUS OR SYPHILIS(?).

Presented by Dr. J. H. BLAISDELL.

Six years ago a man, now forty-two years of age, had a lesion on his penis, which was followed in three months by sore throats, headaches and falling hair. Subsequent to anti-syphilitic treatment by a local physician the lesions disappeared and the patient has been without symptoms until last March, when the present eruption started on the legs, today, the arms, thighs, and lower legs are involved. The eruption is papular, dull red to violaceous and the locations on the legs there is distinct hyperkeratosis and scaling. No angular, flat-topped papules, however, can be noted in any instance. On the inner aspect of the lower left arm there is a three-centimeter annular lesion made up of fairly shiny papules with some superficial atrophy. On the shaft of the penis and on the scrotum there are three, irregular, one-sized lesions, with bluish, raised periphery. The Wassermann test is negative.

#### 9. CONGENITAL SYPHILIS.

Presented by Dr. C. MORTON SMITH.

A young man, nineteen years old, presents extensive scar tissue in the nose and throat. There is a opening between the mouth and nose which allows a certain amount of air through the nose by inhalation, but the patient cannot force any air outward through his nose. A probe cannot find a passage from the mouth to the naso-pharynx.

There is a perfectly smooth mucous membrane extending from the hard palate down as far as one can see. Dr. A. Coolidge states that there is a combination of two processes present. One of the common processes is for the gummatous infiltration in the soft palate to break down and make a large opening from the mouth to the nose. That gives an exaggerated palate. Then there is another condition where the gummatous process starts in the posterior pharyngeal wall.

#### 10. LUPUS PERIO.

Presented by Dr. F. S. BURNS.

Miss K. H. was born in Ireland thirty years ago, and after coming to America developed the present skin affection. The patient's feet become cold in winter, but as yet do not present any lesions. Two years ago the right ear became involved and one year ago the hands. The lobule of the right ear and adjacent skin, for a distance of a half inch in all directions, is involved. The lesion consists of an atrophic cicatrix covered with fine, parchment-like scales and at the lower portion, at the junction with the cheek, the edge is slightly infiltrated, still more scaly and suggests lupus erythematosus. The backs of both hands and fingers, especially the latter, are involved. Both hands show a moderate degree of passive congestion, consistent with a mild pernio. In addition to the pernio there are distributed over the backs of all the fingers, except the ring fingers of both hands, areas of livid red congestion, elevated in most cases, either actively congestive and with vesicular edges or in varying stages of subsidence of the exudative element.

#### 11. CONGENITAL SYPHILIS.

Presented by Dr. ARNER POST.

A case of considerable interest. There is a symmetrical synovitis of the knees. Symmetrical synovitis is fairly common in connection with hereditary disease of this sort. There is rather an exception in the character of the present patient because most of these cases present simply synovitis while the knees are not flexed. Here, however, the knees are flexed and appear to be enlarged. There is considerable heat and an inclination toward a peculiar shape, one joint being a little smaller than the other. There is a slight amount of fluid in the ankle, though very slight.

#### 12. PSORIASIS OF THE PALMS.

Presented by Dr. J. H. BLAISDELL.

A woman, aged forty-five, has six children living and three children dead. The present condition of the hands began one year ago with great itching, and has continued despite treatment. Today the whole palm is covered with a rather moist coating of tiny yellow scales. The lesions extend around onto the back of the hands, where there is, beyond the scaling, a quarter-inch band of dull red infiltration, sharply delineated. On several knuckles there are curious islands of the same dull red infiltration with some puckering and some macerous scaling. There is one small silvery-scaling papule on the elbow. The Wassermann test is negative.

#### 13. ERYTHEMA INDEURATUM SCROFULOSORUM.

Presented by Dr. F. S. BURNS.

On December 15, 1915, Miss R. G., aged twenty-five, was admitted to the Skin Ward of the Massa-

achusetts General Hospital. For eighteen months she had noted deep lumps in the back of the right lower leg. A doctor had prescribed KI. without any improvement and had incised previous similar lesions. At entrance there were three red, hard, tender nodules deep in the skin, besides the scars of the older lesions. The active lesions were thoroughly curetted under ether and the patient was discharged on January 1, 1916. Examination on January 27 revealed the process completely healed and soundly cicatrized.

#### 14. DERMATITIS HERPETIFORMIS.

Presented by DR. C. J. WHITE.

Patient, aged nine, was admitted to the Skin Ward of the Massachusetts General Hospital, November 13, 1915. Nothing remarkable was discovered in his family or past history. The patient gives a very indefinite history of skin trouble at intervals for two years, but during the past summer the skin is said to have been free from eruption of any sort. Beginning in October, the present eruption appeared, and is generalized over the entire body, even in the scalp and on the soles of the feet. It consists of diffusely distributed, erythematous-vesicular rings, varying in size, discrete and confluent, and forming extensive gyrate configurations. Sparsely distributed are crusted areas, probably the site of vesicles, some of which have become infected.

At several different periods since admission the skin has cleared up generally, with the exception of a few vesicular lesions, which appear from day to day. These quiescent periods have been followed by new eruptions diffusely spread over the skin surfaces.

Nov. 13, W.C., 13,400; Polys., 68%; Lymph., 28%; Eosin., 4%; Hb., 70%.

Jan. 20, W.C., 7600; Polys., 43.5%; Lymph., 42%; Eosin., 4%; Hb., 75%; Trans., 10%.

#### 15. HIDRADENITIS DESTRUCTENS SUPPURATIVA.

Presented by DR. C. MORTON SMITH.

Mrs. X., aged twenty-three years, first noticed trouble with her skin when she was eleven or twelve years old. The eruption comes only during the winter months, and has recurred every winter, save one, since the beginning. Many scars of previous lesions are to be found on the feet and lower legs, and a few on the hands. At present there are fifteen to twenty-five active lesions, limited to the feet and legs, and these consist of pinhead-sized, acuminate, pus-topped papules, which leave behind them practically always a smooth, depressed, pit-like scar, resembling closely the scar of acne necrotica.

The general condition of the patient is slightly, if at all, impaired, but her feet are always cold and moist. There is little pain, but much soreness in the lesions, and those going on to pus-formation throb and ache.

Biopsy by Dr. C. J. White four or five years ago showed the condition to be hidradenitis destructens suppurativa,—a process, pathologically tuberculous, involving the sweat glands.

#### 16. DERMATITIS EXFOLIATIVA.

Presented by DR. C. J. WHITE.

In July, 1914, the patient, a woman of sixty, noticed an extensive scabiorrheal (?) condition of the

scalp. In September the skin of the palms of both hands became thickened and exhibited a tendency to fissure and itch. Within a few days the skin over the anterior portions of the chest began to scale, and gradually the process became a universal one. At times the skin showed a tendency to clear up, but relapses always followed. She was treated by a local physician, who prescribed ointment applications with little result. Since onset the condition has never wholly cleared up.

On admittance to the hospital, Feb. 17, 1915, the scalp showed rather well-marked alopecia, and was covered with dirty, greasy-white scales. Upon the face were symmetrical areas of clear skin, that is, above the inner half of each eye and upon the bridge of the nose. Elsewhere the skin was reddened and scaling. The hands showed thick scaling with fissuring of the skin, especially the left. Upon the arms, shoulders, middle of the back and lower legs, the skin was generally erythematous and scaling profusely, particularly upon the legs, which were covered with large scaling plaques. The soles of the feet presented heavy crusting and marked fissuring.

During her entire stay in the hospital exfoliation of the skin continued, with but slight tendency to clear up. At discharge, the patient's general condition was much better than at entrance.

Since leaving hospital in May the patient has applied various remedies to her skin with little change in her condition. She entered the hospital again in August, 1915, and at that time the skin over the entire body, including the scalp, presented a marked erythema, with thickening, dryness and profuse desquamation. The scales varied from small papery scales to large thick plaques. The process was particularly evident over both lower legs, and the folds of the skin in the popliteal spaces showed much fissuring. There was slight ectropion of both lower lids and the conjunctivae were injected.

On re-entrance, treatment with starch baths, i.i.d. and zinc oxide starch powder was begun and followed by some tendency toward improvement in the skin condition. On Oct. 1 all previous treatment was omitted, and the so-called dry treatment, with borated talcum powder and nothing else, was instituted. Under this régime the patient showed steady improvement, until the entire body, save the scalp, was free from scales. To hasten the cleansing of this region, an ointment was applied, contrary to my best judgment, and very shortly the whole disease, in its most aggravated moist form, was back upon us, and for a few days in November the patient's condition became so serious that she was placed upon the "dangerous list." With resumption of the dry treatment, the patient slowly, but only partly, regained her former condition. On April 14, 1916, the skin of most of the body is red and somewhat scaly, but in June the patient reported herself wholly recovered.

On entrance, W.C., 7800; Hb., 60%; Polys., 66%; Monos., 26%; Eosin., 8%; Trans., 6%.

January 27, W.C., 10,800; Hb., 65%; Polys., 52%; Monos., 34%; Eosin., 12%; Trans., 2%.

#### 17. EPITHELIOMA(?)

Presented by DR. BOARDMAN.

The patient is a man sixty-seven years of age, who began to have trouble with his leg forty-seven years ago. An ulceration developed on the front of

the leg, gradually worked around, but finally healed under various forms of treatment, and remained well until two years ago, when it broke down again. At present there is an area on the back of the leg which at no time has shown any ulceration, but has been covered with cheesy, necrotic material, which, if left alone, grows about an inch thick. If this material is removed one finds a fungating appearance underneath. The patient has refused to have a biopsy made.

Dr. Boardman believes that the disease is an epithelioma which developed from a nevus, which ulcerated and then changed over into an epithelioma. Amputation has been advised but refused.

#### 18. THE NEW TREATMENT OF PSORIASIS BY A NON-CARBOHYDRATE DIET.

Presented by Dr. L. J. CUMMINS.

The patients were placed in the ward and at first given starvation diet with whiskey and water every two hours for the first two days. It was astonishing how the patients stood this starvation. Later we began the treatment without the starvation diet. We began with carbohydrates, twenty grams for three days, then increased to thirty, kept on that three or four days, and then worked up to forty. When the psoriasis did not respond as quickly, we restricted the amount to twenty grams.

The patient presented has been in the ward for four weeks. At entrance she was almost completely covered with heavily scaling lesions. The scaling was quickly diminished and the remaining large erythematous plaques are breaking up very rapidly, while no infiltration has lessened. All the patients who have been under our care in the ward have done very well. We have had over eighty cases in the out-patient Department who have all been given a diabetic diet, and those who have followed the diet have responded very well. When starch and carbohydrates are reduced the expense of food diet is actually doubled.

Dr. TOWLE: What has been done in other respects? How about other food substances?

Dr. CUMMINS: Proteids, between fifty to one hundred grams. Fats, between 100 to 200, bringing a calories up to between two to three hundred.

Dr. OLIVER: How much weight have these patients lost?

Dr. CUMMINS: Between four and ten pounds during their stay in the ward. The patients who started on starvation diet cleared up more quickly than those put on the limited diet. There has been no external or internal medication.

#### 1. THE TREATMENT OF ACNE ROSACEA BY RONTGENIZATION.

Presented by Dr. L. J. CUMMINS.

We have had eight cases in our series, which we have been treating by x-ray exposure to the thyroid. Patients were from twenty-five to thirty-five years of age. The first patient had distinct hyperthyroidism and was sent to x-ray for treatment. After the first x-ray exposure rosacea was markedly less. Since then I have been observing cases and sending them to x-ray for treatment. They all had shortness of breath on exertion, fine tremor, rapid pulse, and were highly nervous. The interval between exposures has been from two to three weeks, so that one has had three treatments.

The subjective symptoms of itching and burning

have ceased after the first exposure, and we have seen improvement in all cases so far, but have not followed these exposures long enough to note any cures.

Dr. TOWLE: Do you expose the nose or cheeks?

Dr. CUMMINS: The radiations have been limited to the region of the thyroid gland.

CHARLES J. WHITE, *Secretary*.

### Book Reviews.

#### *Changes in the Food Supply and Their Relation*

*To Nutrition.* By LAFAYETTE B. MENDEL, Professor of Physiological Chemistry in the Sheffield Scientific School. New Haven: Yale University Press. 1916.

This monograph is an essay written for the meeting of the Second Pan-American Scientific Congress in Washington, in December, 1915. The author points out that the three fundamental conditions of modern civilization are food supply, sources of mechanical energy or power, and methods of transportation. The purpose of his essay is to show the effect which modern preservatives and transportation facilities have had on the food supply and on the possibilities of nutrition of civilized mankind. The fact that well-to-do communities have the resources of practically the entire world at their command at all seasons of the year, not only has an extensive economic effect, but upon the dietetic changes that result may depend important biologic evolutionary alterations. Dr. Bryant and others have recently pointed out the variations in physical form which may be determined or at least largely influenced by dietetic conditions. Perhaps the most interesting and timely portion of this work is that referring to food conditions as at present prevailing in the central European empires during the blockade to which they are subjected as a result of the war. The author comments particularly on the scientific acumen of the German nation in its public propaganda to meet the situation thus created. Especial reference is made to the German literature which has already arisen on this subject, to which the principal contributors are Drs. Eltzbacher, Oppenheimer, Rubner and Zuntz. The volume is of distinct value as a contribution to the study of modern dietetics and economics.

*A Purin Free Dietary.* By EDNA ALICE WAITE AND ROBERT ELSWORTH PICK, M.D. Woodmont, Conn. 1916.

This manual consists of a purin free diet list, a series of sample menus and a collection of recipes for making the dishes prescribed in a purin free diet. It should be of interest and value to dietitians and a convenience to physicians dealing with cases requiring such treatment.

## THE BOSTON Medical and Surgical Journal

Established in 1812

An independently owned Journal of Medicine and Surgery published weekly under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, NOVEMBER 23, 1916.

### EDITORS

ROBERT M. GREEN, M.D., *Editor-in-Chief*  
GEORGE G. SMITH, M.D., *Assistant Editor*  
WALTER L. BURRAGE, M.D. *For the Massachusetts Medical Society*

### COMMITTEE OF CONSULTING EDITORS

WALTER B. CANNON, M.D.      ALLAN J. McLAUGHLIN, M.D.  
HARVEY CUSHING, M.D.      ROBERT B. OSGOOD, M.D.

**SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States. \$6.50 per year for all foreign countries by *air* mail, *postpaid*.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, Manager,

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

## ELECTRIC DELINEATION OF VISCERA.

In the issue of the *British Medical Journal* for September 30, 1916 (page 459), was published an article describing the work of Dr. James Shearer at a casualty clearing station in France on a new method of electric delineation of the internal organs of the body. This method, which utilizes the electricity of the body, suggests a combination of wireless telegraphy and electric photography, yet, in reality, it has no relation to either of these. Indeed, it succeeds at exactly the point where x-ray photography fails, in that it enables the production of pictures of soft organs and other structures far within the surface of the body. In these pictures general outlines are exceedingly clear, but no details are visible.

What the work seems to do in its present stage is to enable it to be stated, without any manual or other examination, whether the more important viscera of a living patient—such as the

liver, the kidneys, the spleen, and the brain—are intact so far as their gross anatomy is concerned, while at the same time it supplies evidence of any departure from the normal, in the nature of a considerable enlargement or diminution in size, or an effusion of blood, or the presence of a foreign body, or the existence of a tear or rent of the visceral surface.

The inventor states his belief that the results are primarily due to the interposition between two alternating electric fields of equal strength, and at the precise point where these fields meet, a third electric field, whose facultative potential force is thus released, and becomes convertible into dynamic power. This released circuit operates a recording needle, which maps out on a revolving cylinder a pattern varying with the shape of the organ which furnishes the circuit. The appliances employed are two electric batteries of precisely equal strength, whose current alternations can be produced and varied at will. Two electrodes are arranged for application to the patient's body, each connected with a perforated zinc plate or a zinc wire screen. One of these screens stands vertically on a movable pedestal. The other is held in the air by wire supports and is movable in a horizontal position four or five feet above the center of the first screen (screen A). Any electric field emanating from screen A is, therefore, always at right angles to that of screen B, the currents supplying these fields being derived from the two batteries, with their alternating interruptors. From one of the electrodes a wire is led to a revolving drum resembling a barograph, over which is suspended a needle hammer capable of lateral as well as vertical motion. The drum cylinder carries a rolled sheet of paper coated with paraffine, on which the outline of the organ is to be recorded. The needle hammer is connected with a carbon diaphragm like that of a telephone, which, in its turn, is operated by a current detector, capable, not only of picking up and measuring, but also of concentrating currents too small to be convertible into force by any other means. The method of operation of this apparatus is described in the original article as follows:

"The first step is to place the patient in the right position in relation to the two screens. He must be quite close and head on to the vertical screen A, and the organ to be examined must be directly under screen B, though at a considerable distance from it, and at the same time present the desired plane towards screen A.

"The right position having been secured, the following steps are taken: (1) An intact wax sheet is put upon the recording cylinder; (2) the rate at which the cylinder shall revolve is determined; (3) the appliance which regulates the rapidity of the alterations is adjusted; (4) the currents from batteries A and B are simultaneously released, with the immediate result that the recording cylinder begins to revolve while the hammer needle moves across it steadily, giving rise at each stroke to a slight click. This movement of the needle is allowed to continue until it has twice traversed the cylinder from end to end, and the currents are then cut off.

"What has happened in the mean time is that the current from battery A has reached the electrode A, and has thence been projected horizontally from all parts of screen A as an electric field. The same thing has happened in regard to the current from battery B, but the direction of the field projecting from screen B has been vertically downwards.

"What has also happened is that the two fields have met at right angles, and as they are of precisely equal strength, and are synchronized in respect of alternations, it might be expected that they would have precisely neutralized one another, and that consequently no exhibition of dynamic force would be obtainable from them.

"But in practice this is not what occurs. On the contrary, provided that the body under examination is that of a living person (or is one in which merely somatic, not cellular, death has occurred), an effective current from below always manages to reach electrode B, and thence passes to the detector.

"The result, therefore, has been that the hammer needle mentioned has been put into operation and has tapped out on the revolving wax sheet below it a diagram which precisely resembles the outline of the living tissues lying vertically below screen B.

"This diagram can be discerned forthwith by holding the wax film against a strong light, and can be converted into an ordinary photograph by processes of a type quite familiar in various applied arts."

The inventor's view of this process involves the supposition that every organ in the body constitutes and originates a separate electric field, and that the facultative, dynamic power of this field, and also its shape, varies precisely with the constitution and shape of each organ.

"The explanation here given may be insufficient to account for all the results, or even to be in direct conflict with accepted views concerning body electricity. But, after all, very little is at present known concerning organic tissues as a source of electrical force, and in any case the fact remains that it is on this theory that the

inventor and the originator of the process has worked out his discovery and is at present endeavoring to perfect it in respect of mechanical details.

"While the greater part of the process has been developed by constructing a novel theory and converting it into a practice, a good many of the results so far obtained are due to experiment. It has been found, for instance, that the appliances must be tuned for different organs and different tissues.

"In other words, the rate of alternations in the currents, and therefore the force of each electrical impulsive, must be varied according to the rate of vibration of the tissue molecules. Thus the electrical force residing in blood is very small; so, when blood vessels are to be delineated, the alternations must be very rapid. Contrarywise, since the electric force residing in heart muscle is great, the alternations must be slow when a heart is to be delineated."

The practical value of this peculiar and brilliant discovery promises to be considerable. Further report on the employment is announced to appear in an early issue of the *British Medical Journal*. If experience bears out early expectations, this discovery should open a new field of diagnosis, which may prove applicable in many diverse conditions, not only surgical but medical.

It is of interest that the discoverer of this new method, a Scotsman by birth, obtained his medical education in the United States, receiving the degrees of M.D. and Ch.M. at the University of Washington in 1907. At the outbreak of the European War he entered the British Army Medical Corps as a sergeant. His special electrical knowledge, however, and the use which he made of it in the development of his invention, led speedily to the recognition of his ability, and he has recently been commissioned as a captain.

#### PREVENTION AND RELIEF OF HEART DISEASE.

IN the weekly bulletin of the New York Health Department for November 11, 1916, is published a preliminary account of the work of the committee of this department for the prevention and relief of heart disease. A program has been outlined by this committee dealing with the provision of suitable occupation for cardiac patients, the organization of cardiac classes, the increase of opportunity for cardiac patients in convalescent institutions, and the

provision of permanent institutional care for cardiac patients with permanently broken compensation and little or no prospect of future restoration. In addition, it is hoped that a way may be found to keep all public playgrounds open for the entire year. In comment upon this work the bulletin says:

The Committee's program is of special interest now that public attention is focused on the after-care of poliomyelitis. For the latter, as our readers know, funds have been forthcoming from many different sources. As a matter of fact, the problem presented by the proper care of cardiac cases is the more important of the two. It is estimated that there are about 20,000 children alone suffering from heart disease and requiring systematic care. In a number of ways the two groups need similar provision for relief. Thus both groups should be under constant social and medical supervision; the members of both groups should be fitted for occupations suited to their infirmity; some of the children in both groups need to be taken to school in conveyances. Altogether, it would seem likely that a similar plan of procedure would be developed, especially that a way be found to coordinate the work of existing agencies to the fullest extent.

As one of the many phases of disease prevention and control, the work of this New York committee deserves the interested attention of the profession to the possibilities of its accomplishment.

#### PROGRESS OF POLIOMYELITIS.

DURING the past week the epidemic of poliomyelitis in Massachusetts has continued to decline. During the first seventeen days of November, 139 cases were reported, giving a total of 1854 since the beginning of the year.

On November 11 the Massachusetts State Department of Health announced that, in conjunction with the Harvard Infantile Paralysis Commission, it purposes to open a clinic in Boston for the after-care of recovered cases of poliomyelitis. The complete statement issued is as follows:

"As previously announced, the Governor and Council gave the State Department of Health \$5000 from the contingent fund with which to inaugurate a system of after-care of patients suffering from infantile paralysis. This year there have been in the State more than 1700

cases of this disease, a figure much in excess of any previous years. Of the non-fatal cases a considerable majority will suffer a varying amount of permanent defect. With proper treatment the amount of defect may be reduced and, in some cases, wholly avoided.

"Because of the hitherto comparatively infrequent occurrence of this disease, experience in the treatment of the disease has been limited.

"For this reason it seems desirable to offer opportunity for all patients to receive the most skillful treatment possible. To this end the State Department of Health has joined with the Harvard Infantile Paralysis Commission in providing a series of clinics to be located in Boston and at points outside the Metropolitan area where physicians may bring their patients for consultation and advice as to treatment. Patients will be received only with the consent of the attending physician.

"The work of the clinics will be under the supervision of the Harvard Infantile Paralysis Commission, with skilled surgeons in attendance at the clinics, together with nurses especially trained for the work, to assist at the clinics, to care for the follow-up work in the homes and to instruct patients and their parents as to exercise and treatment advised. Where physicians are unable to accompany their patients to the clinic, the suggestions will be communicated to them by letter.

"The members of the commission are Roger Pierce; Dr. F. W. Peabody, who is interested in the care of acute cases; Dr. R. W. Lovett, who is particularly interested in the after-care of infantile paralysis; and Dr. M. J. Rosenau, who is especially interested in the study of the disease and research problems.

"The Boston clinic will probably open on November 23 at the Children's Hospital. The hour and place, as well as the time and location of the clinics outside of Boston, will be announced later."

#### MEDICAL NOTES.

LONDON DEATH RATES IN SEPTEMBER.—Statistics recently published show that the total death rate of London in September, 1916, was only 12 per thousand inhabitants living. Among the several districts and boroughs the highest rate was 16.6 in Poplar, a populous East Side slum, and the lowest was 6.7, in the central region of the city.

AMERICAN ELECTRIC-THERAPEUTIC ASSOCIATION.—At the recent annual meeting of the American Electro-Therapeutic Association the following officers were elected for the ensuing year:

President, Dr. J. Willard Travell, New York.  
 Vice-Presidents, Dr. William Martin, Atlantic City, N. J.; Dr. Frank B. Granger, Boston;  
 Dr. Frank E. Peckham, Providence, R. I.;  
 Dr. William L. Clark, Philadelphia; Dr. A. B. Hirsh, Philadelphia.  
 Treasurer, Dr. Emil Henel, New York.  
 Secretary, Dr. Byron S. Price, New York.  
 Registrar, Dr. Frederick M. Law, New York.

**NATIONAL BOARD OF MEDICAL EXAMINERS.**—The National Board of Medical Examiners held its first examination at Washington, D. C., on October 16-21. There were thirty-two applicants representing twenty-four medical schools from seventeen states. Of these, sixteen candidates were accepted as having the necessary preliminary and medical qualifications. Ten of these took the examination and five passed. The second examination will be held at Washington in June, 1917. Further information may be obtained from the secretary of the board, Dr. J. F. Rodman, 2106 Walnut Street, Philadelphia.

**UNIVERSITY OF CHICAGO MEDICAL SCHOOL.**—Report from New York on November 10 states that the General Education Board, in cooperation with the Rockefeller Foundation, has appropriated the sum of \$2,000,000 for the establishment of a medical school at the University of Chicago. The University itself is to appropriate the same amount and to furnish a site of land valued at \$500,000. An additional sum of \$3,500,000 is to be raised which, with funds already in hand, will furnish an initial endowment of \$8,000,000. On November 14 it was announced that Mr. Julius Rosenwald of Chicago, one of the trustees of the University, had given \$500,000 towards this endowment fund.

#### EUROPEAN WAR NOTES.

**VICTORIA CROSS FOR BRITISH SURGEONS.**—In the issue of the *Lancet* for October 28, announcement is made of the recent award of the Victoria Cross to two British surgeons. The first award is to Dr. William Barnsley Allen, M.C., R.A.M.C., a medical graduate of Sheffield University, "for most conspicuous bravery and devotion to duty. When gun detachments were unloading H. E. ammunition from wagons which had just come up, the enemy suddenly began to shell the battery position. The first shell fell on one of the limbers, exploded the ammunition and caused several casualties. Captain Allen saw the occurrence and at once, with utter disregard of danger, ran straight across the open, under heavy shell-fire, commenced dressing the wounded, and undoubtedly by his promptness saved many of them from bleeding to death. He was himself hit four times during the first hour by pieces of shells, one of which fractured two of his ribs, but he never even mentioned this at the time, and coolly went on

with his work till the last man was dressed and safely removed. He then went over to another battery and tended a wounded officer. It was only when this was done that he returned to his dugout and reported his own injury."

The second award was to Dr. Noel Godfrey Chavasse, M.C., R.A.M.C., a medical graduate of Oxford, "for most conspicuous bravery and devotion to duty. During an attack he tended the wounded in the open all day, under heavy fire, frequently in view of the enemy. During the ensuing night he searched for wounded on the ground in front of the enemy's lines, for four hours. Next day he took one stretcher-bearer to the advanced trenches, and under heavy shell-fire carried an urgent case for 500 yards into safety, being wounded in the side by a shell splinter during the journey. The same night he took up a party of 20 volunteers, rescued three wounded men from a shell-hole 25 yards from the enemy's trench, buried the bodies of two officers, and collected many identity discs, although fired on by bombs and machine-guns. Altogether he saved the lives of some 20 badly wounded men, besides the ordinary cases which passed through his hands. His courage and self-sacrifice were beyond praise."

**A GERMAN UNDERGROUND HOSPITAL.**—A recent issue of the *Medical Press and Circular* quotes from the *London Morning Post* the following account by a British surgeon of a German subterranean hospital at Thiepval, captured during the recent British advance. At first the medical staff of the hospital succeeded in removing all its patients to a place of safety. Later, the surgeon-in-chief and his colleagues were captured and brought back to their former hospital as prisoners.

"The hospital lay two storeys below the ruins of Thiepval—a wide, clean room, lit by candles and small hand-lamps, with every imaginable requisite of a field dressing station at hand. There were drugs unobtainable in England; anti-tetanus and other serums in plenty, oxygen, piles of fresh dressings, surgical instruments neatly arranged beside an operating table—everything except a pair of scissors!"

"Throughout the first night of the British occupation this surgeon worked in the theatre so thoughtfully provided by his enemies. At dawn there was a slight commotion outside. Down a gap leading to the entrance of the hospital dug-out came a German army surgeon, followed by his full staff of twenty orderlies and dressers, pointing to their Red Cross armbands and calling out 'Kamerad!' With the precision of a pre-arranged relief the German staff 'carried on.' A wounded British officer near by was taken in hand by the Württemberger surgeon, who returned to his lamp-lit surgery and began dressing injuries with skilful speed. He was a valuable assistant, and his British colleague pays this tribute to his work."

THE PLIGHT OF POLAND.—Throughout the Kingdom of Poland there is a ratio of 240 deaths to 100 births, declares the late Henryk Sienkiewicz, the distinguished author of "Quo Vadis," in a leading article in the *American Red Cross Magazine* for November, entitled "Behold our Poland!"

"The present war has inflicted injuries on nearly all the peoples of Europe," says Mr. Sienkiewicz, "but on none of them have the calamities pressed so heavily—with a weight as intolerable—as on the Poles, a people of twenty-odd millions, divided between Russia, Austria, and Prussia.

"Belgium and Serbia were devastated by sword and fire, but the storm which passed over these two countries was of short duration, and the Belgian and Serbian soldiers had, at least, the consoling thought that they were giving their lives 'for altars and firesides' in defending their own liberties and their own rights. To the Poles such a consolation was denied. Nearly two millions of Polish soldiers have been drafted in three armies, and in consequence have been forced into a fratricidal struggle.

"Even if Polish territory had not become the theatre of war, this fact alone would constitute a crown of misfortune. But it is precisely on our territory that the struggles have been the most intense, where they have endured the longest, and are again to be renewed. To prevent the rationing of belligerents, the villages and towns have been burned, crops in the granaries and in the fields destroyed, and cattle driven off. They have razed the factories, and those which are standing have been forced to suspend operation in default of raw material and because their machinery has been taken away. As an inevitable consequence of desolation, famine and epidemic prevail throughout Poland.

"In addition to cholera and typhus fever, which, in certain districts, notably in Galicia, are decimating the population, a new malady has made its appearance in our country—the terrible malady of hunger—whose symptoms preceding death are the floating of the body and blindness. Dr. Strauss, of the German Government, has given a precise description of this malady in the *Zeitschrift für ärztliche Fortbildung*. Throughout the Kingdom of Poland the statisticians report a ratio of 240 deaths to 100 births. When the Russians in retreat, pressed by the Germans, took along with them the civil population inhabiting the right bank of the Vistula River, a majority of the children died of hunger, fatigue, and malnutrition. The same happened in the concentration camps of Austria and Prussia.

"For remedying, even in part, this horrible situation, a 'General Aid Committee for the Victims of the War in Poland' was constituted in Vevey, Switzerland, January 9, 1915, under my direction and under that of M. Pader-

ewski. This committee addressed to all civilized people an appeal, signed by myself, asking, in the name of the State of Poland, in view of its merits as a Christian bulwark against the barbaric hordes, as well as its achievements in the domain of science, of art, of progress in general, and of civilization, to succor this people menaced in its very existence.

"Our appeal was not without echo. It was supported by Catholic churches throughout the Christian world. From January 9 to July 1, 1916, we had collected the sum of 12,571,276 francs (\$2,514,253.10), of which amount we had sent, up to the latter date, the sum of 12,137,044 (\$2,427,408) for aiding in Poland the population deprived of shelter and those suffering from hunger without making any distinction between the religions.

"Subsidies in money have been sent to the territories occupied by the Germans and Austrians in Galicia and Lithuania, and to the Poles taken by the Russian Army into Russia; also to those in the concentration camps in Austria. We have obtained in Switzerland authorization to send thirty wagons of condensed milk for the little children. This consignment has been received by the mothers with transports of joy in all the localities of Poland where misery has made itself felt the most. We invariably have sent money, clothing, and provisions destined for Poland to the local committees presided over by Poles of distinction."

Mr. Sienkiewicz declares emphatically that no part of the Polish relief supplies have been requisitioned or confiscated by the belligerents or their armies, and he adds that had one instance of this kind been brought to his attention he would have suspended further consignments of relief stores and dissolved the General Aid Committee for the Victims of the War in Poland.

What the relief agencies have been able to do for the stricken Poles, Mr. Sienkiewicz says, of course, has been woefully inadequate "to alleviate in an efficacious manner the frightful misery which has attacked the millions of our compatriots. Throughout the Polish provinces," he says, "the people, even those with very scanty means for staving off famine, divide what little they have with the poorest of their brethren.

"In America," he continues, "thanks to the devotion and energy of such individuals as M. and Madam Paderewski, Madam Sembrich-Kochanska, Madam Adamowski, and numerous Polish associations, compassion for the tragic fate of our people grows each day more and more, and finds its expression not only in a large material support, but also in the expressions of your most eminent citizens, who raise their voices in defense of our existence and of our right to independence. The noble efforts of President Wilson and Ambassador Gerard definitely to heal the wound of famine in Poland were powerless to vanquish the obstacles which rear themselves in time of war—the selfishness

of the belligerents; but they fill our hearts, nevertheless, with gratitude. We entertain the same sentiments toward your American Red Cross, which several times has forwarded contributions in money and clothing to our committee.

"The fraternal compassion of your country, in which at present takes refuge not only the humane conscience banished from Europe, but also the spirit of Christian charity, fills us with hope and fortifies us in our most bitter hour. The situation of Poland is horrible! However, if the civilized people, jointly and severally answerable to humanity in its entirety, do not cease to regard our cause as they do their own, we will cling fast to the end, and we ourselves will awaken soon, full of force, and ready for a new life in liberty."

**WAR RELIEF FUNDS.**—On November 18 the totals of the principal New England relief funds for the European War reached the following amounts:—

Belgian Fund .....	\$167,447.58
French Wounded Fund .....	142,083.87
Armenian Fund .....	124,251.38
Surgical Dressings Fund .....	57,509.06
Polish Fund .....	47,300.75
LaFayette Fund .....	29,653.53
Russian Refugees' Fund .....	4,917.17

### Massachusetts Medical Society.

#### MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY.

—At the October meeting of the Middlesex South District Medical Society a special committee was appointed with power to call meetings of members for the purpose of informing them in regard to the proposed social insurance laws. The Committee consists of the following members:

Dr. Charles E. Mongan, Somerville, Chairman; Dr. Frank E. Bateman, Somerville; Dr. Frank W. Plummer, Malden; Dr. Felix McGirr, Cambridge; Dr. Henry A. Wood, Waltham; Dr. P. C. Barthet, Newton Highlands; Dr. Enos H. Biselow, Framingham. Dr. John F. O'Brien, Charlestown.

This committee has already met with local medical societies in the Middlesex South district and is ready to visit, on request, other societies or groups of medical men who are interested in the above-named legislation. Also, on request, it will furnish references to recent literature on the subject. Application for either of these purposes should be made to the chairman.

#### BOSTON AND NEW ENGLAND.

**WEEK'S DEATH RATE IN BOSTON.**—During the week ending Saturday noon, Nov. 18, 1916, the number of deaths reported was 200 against 203 for the same period last year, with a rate of 13.72 against 14.14 last year. There were 32

deaths under one year of age against 40 last year, and 58 deaths over 60 years of age against 63 last year. The number of cases of principal reportable diseases was: Diphtheria, 38; scarlet fever, 18; measles, 14; whooping cough, 10; typhoid fever, 3; tuberculosis, 30. Included in the above were the following cases of non-residents: Diphtheria, 12; tuberculosis, 3; scarlet fever, 5.

Total deaths from these diseases were: Diphtheria, 4; tuberculosis, 18. Included in the above were the following deaths of non-residents: Diphtheria 1; tuberculosis, 3.

**AFTER-CARE OF INFANTILE PARALYSIS.**—Beginning on December 1, 1916, the Orthopedic Department of the Children's Hospital, Boston, will offer a course in muscle training and in the principles of the nursing after-care of infantile paralysis. This course will be open to a limited number of properly qualified women, and will be an all-day course covering a period of about six weeks, most of the work being in the clinics and practical in character.

The money received will be used for the maintenance of the clinic. Pupils who are not likely to prove satisfactory practical workers will be advised to withdraw early in the course and their fee will be returned to them. The course will be under the general supervision, but not under the actual instruction, of Dr. R. W. Lovett, Surgeon to the Hospital, to whom application for admission should be made at the Hospital.

**JOINT PEDIATRIC MEETING.**—Under the auspices of the New England Pediatric Society there was held in Boston, on November 4, a joint meeting of that society with the Pediatric Society of the New York Academy of Medicine, the New York State Pediatric Society and the New Jersey and Philadelphia Pediatric Societies. Visits were made in the forenoon to the principal pediatric clinics of the city. Luncheon was served at the Harvard Medical School and the afternoon was devoted to a trip to the Massachusetts School for the Feeble-minded at Waltham. Dinner was served at the Harvard Club. At the evening session, held in the Boston Medical Library, the principal addresses were made by Dr. G. Hudson McEwen of Philadelphia, Dr. Fenton B. Turk of New York and Dr. W. G. Smilie of Boston.

**MASSACHUSETTS HOMOEOPATHIC HOSPITAL.**—The 46th annual report of the Massachusetts Homoeopathic Hospital, covering the year ended December 31, 1915, has recently been issued. It records a total number of in-patients treated of 7917, making the total number of in-patients treated since the opening of the hospital in 1871 82,928. This was a gain over the previous year of 382 patients. The contagious department treated 1138 patients, a gain of 300 over the

previous year. The new maternity hospital, dedicated on January 1, 1916, supplies accommodation for 76 patients. The operation of this new building has called for added accommodations for increased hospital staff and nurses, and to meet these needs an adjoining building has been purchased. It is also planned to erect a new building to provide for dining-rooms, kitchen and laundry, as well as all machinery, including lighting plant and storerooms. The space now occupied by these departments will be used for much-needed hospital purposes, and will permit the arrangement of a surgical operating pavilion with amphitheatre and smaller operating rooms.

**ANTI-VACCINATION INQUIRY.**—At a recent meeting of the Boston Homeopathic Society the following resolution, relative to the attitude of members of the Massachusetts General Court on anti-vaccination legislation, was adopted:

"Whereas, certain articles of legislation, vitally affecting the public health, will be presented to the incoming Legislature, and,

"Whereas, we physicians, intrusted as we are, with all that pertains to the public health, therefore be it

"Resolved, That the members of this Society, and all other physicians, be requested to ascertain before election the status of each candidate to the Legislature from his senatorial and representative district, on the anti-vaccination bill and the Pang Suey bill, so called, and that each physician be requested to use his influence against any candidate favoring said legislation."

**HOSPITAL BEQUESTS.**—The will of the late Ellen Bailey, who died at West Roxbury, Mass., on October 24, contains bequests of \$2000 to the Children's Hospital, Boston, and \$1000 to the Dorchester Home for Incurables.

The will of the late Louisa F. Crane of Dalton, Mass., which was filed in probate at Pittsfield, Mass., on November 8, contains bequests of \$15,000 to the House of Mercy Hospital, Pittsfield, and \$5000 to the Perkins Institute for the Blind, Boston.

**MORBIDITY STATISTICS OF BOSTON.**—There has recently been completed in Boston by Dr. Lee K. Frankel and Dr. Louis I. Dublin of the Metropolitan Life Insurance Company, through the work of 300 agents, a canvass of nearly 100,000 inhabitants of Boston, with reference to health and morbidity conditions in this city. This survey, which involved house visits on 20,497 families, representing a total of 97,259 individuals, or about 13% of the estimated population of the city, was presented at the recent convention of the American Public Health Association in Cincinnati.

"In all, 1902 cases of sickness were recorded, this being equivalent to a rate of 19.6 persons

sick in 1000 persons canvassed, or under 2%. The report then states that the rate as a whole is distinctly lower than in the surveys made in other cities; the lowest previous rate being 23.1 per 1000, for Rochester, N. Y. The report adds that the very favorable condition shown for Boston may, in part, be the result of the survey being taken in mid-summer, when low mortality and a small number of respiratory disorders usually prevail. The report says nothing, however, of the infantile paralysis epidemic which prevailed in July, as the survey was made in the two weeks beginning July 17 and 24.

Of the 1902 cases of sickness discovered, 1747, or 91.9%, were disabled for work, and 155, or 8.1%, were reported sick but able to work. This indicates a higher percentage of "unable to work" cases than in other surveys, but the report states that the increase is due to the changes in classification whereby some cases returned with ability to work were formerly classified as "unspecified" are now classified as "unable to work."

Concerning the economic loss from sickness in this city the report states: "The estimated male population of Boston, 15 years and over, in 1916 is 272,219. On the basis of the sickness rate determined by this survey for these ages (21.6 per thousand) we may conclude that there are at least 5880 males in Boston constantly sick and disabled. At 300 working days per year per individual, there is a loss of 1,764,000 working days, or 6.5 working days per individual.

This average of time lost for sickness and accident in the general community may be compared with 7.6 days in North Carolina and 7 days in Rochester, N. Y.

"The latest available figures for males of working age in the local sick benefit societies of Germany, namely, for the year 1913 (the year before the war began), shows an average of 8.8 days of disability for work per year.

"In like manner, the 286,081 females of working age may be expected to give a total of 6237 persons constantly sick, which, at 300 working days per year per individual, gives a total loss of 1,871,100 working days, or an average of 6.5 days per individual per year. The corresponding figure for the Rochester survey was 7.7 days; for North Carolina, 10.2, and for the latest German Sickness Society experiences, 9.8 days."

The report also states that the principal diseases responsible for the sickness registered were rheumatism, organic disease of the heart, tuberculosis of the lungs, diseases of the kidneys, and diseases and conditions of the puerperal state.

It also states: "The proportion of cases of sick less than one month up to the date of the survey was only 26.3% of the total. This was slightly higher than the finding for Rochester,

N. Y., but considerably lower than the proportion of cases sick less than one month in North Carolina. The relatively small number of cases of the acute infectious diseases accounted for this condition.

"Of the total cases 72.9% received medical attention; this is a higher percentage than that developed in the preceding surveys. This finding reflects the excellent medical facilities available in the city of Boston. Hospitals and dispensaries provided a large proportion of the total amount of medical care."

The report shows also that among the males 19.9 persons were sick for each 1000 exposed; the figure for females was 19.5 per 1000. Sickness involving disability for work occurred at a rate of 18.1 per 1000; the same rate of sickness was observed for females.

Tuberculosis of the lungs was found in 82 cases, or at the rate of 84.3 per 100,000, and the report states that this is the lowest tuberculosis rate so far discovered in the several surveys. The report adds, "The medical care of tuberculosis cases is apparently well developed in Boston."

According to the report the city of Boston was chosen for the survey "because of its large and representative population, its geographical location and its varied industrial activity. The appointment of a Special Commission on Social Insurance by the Governor of Massachusetts to report on health insurance among other matters, suggested the possibility that our findings for Boston might be especially useful to this body in its studies. Finally, the excellent medical facilities of Boston, including hospitals, dispensaries, a well-developed nursing association and other health and social agencies, confirmed our decision to make our study there. It was hoped that the facts developed by our inquiry might be put to practical use by placing data obtained at the disposal of these institutions."

## Correspondence.

### WORKINGMEN'S COMPENSATION.

November 9, 1916.

Mr. Editor:—

Apropos of the report of the Committee on the Workingmen's Compensation Act in this week's *JOURNAL*, it may interest the members of the Massachusetts Medical Society to know that, on June 9, 1916, a man testified, under oath, before the Industrial Accident Board, that he was so busy doing surgical work at an industrial plant that he did not have time to make the customary report of accidents to the Industrial Accident Board. When asked why he did not send accident cases to a doctor, he said that he was doing dressings under the direction of the attorney for the company.

This special law violation was brought to the attention of the State Board of Registration in Medicine some six months ago, but evidently the welfare of the workman and the medical profession is of small concern to this Board.

That it is a common occurrence for unauthorized persons to practice surgery and medicine throughout the state is evidenced by the statement of the attorney of the insurance company at the hearing previously alluded to, that trained nurses treated cases for them right along and that they had no complaints. The man above mentioned, by the way, is not a trained nurse.

The "old line" companies are, as a rule, treating the local physicians well, but the mutual companies are resorting to the most unfair methods, both as regards the injured workman and the doctor.

A scheme which the two mutual companies work together is to have a dispensary inconveniently located. When a man is injured, he is directed to go to this place, often miles from the factory where the man is injured. The man usually gets sick of the treatment and the time lost in visiting this dispensary. He goes to his family doctor. If the family doctor tries to collect a fee from the insurance company before the Industrial Accident Board, the insurance attorney will say: "You can't beat Dr. So-and-So"—mentioning a very prominent surgeon,—giving the Board the impression that the insurance companies' cases are treated individually by this surgeon, when, as a matter of fact, the same surgeon does scarcely any of that work at all.

I think that the doctors have had about enough of the so-called state and mutual companies. Instead of furnishing regularly qualified physicians to treat their injured workmen, they have used nurses, social workers, ex-painters—anything to save a few cents—with the result that the afflicted workmen fall back on the family doctor and the doctor cannot collect a cent from the insurance companies because the companies furnish a dispensary to cover the law, or, rather, to evade the law.

It was most fortunate that the Legislature allowed the standard insurance companies to write insurance under the Workingmen's Compensation Act. Physicians would be in a sorry plight today had all this business, as was first intended, been taken over by the state company. I can imagine a chain of cheap dispensaries over the state with a corps of nurses and orderlies, operated from headquarters.

There is great room for improvement in the enforcement of the Medical Practice Act. A great many people think that nerve is more necessary than knowledge and a license to practice medicine in Massachusetts, and I don't know but that it is true.

Very sincerely,

CHARLES MALONE, M.D.

5 Glen Road, Jamaica Plain, Mass.

### AMMONIUM SALICYLATE IN POLIO-MYELITIS.

November 10, 1916.

Mr. Editor:—

I have now much corroborative proof that salicylate of ammonium, given in sufficient doses, at the inception of infantile paralysis, is of great practical value. It is, as yet, the simplest, least objectionable remedy offered. It interferes with nothing else that is rational. No doubt Dr. Lovett's admirable work is most desirable when paralysis has occurred; but why not prevent it, or, at least, greatly diminish its severity?

Please read "Grip in Children," *Journal American Medical Association*, Oct. 28, 1916 and discussion which follows, and you will agree with me that there is to be found not a little that is illuminating.

Theories of disease are one thing; practice, based upon long and varied experience, is another. I have never seen in grip or gripe, any drug so valuable as the salicylate of ammonium; and allow me to add, my experience has been neither small nor restricted.

Very truly yours,

BEVERLY ROBINSON, M.D.

New York, 12 West 57th St.

## HARVEY'S JOURNEY TO PADUA.

Mr. Editor:—

The following incidents concerning the life of Harvey are from a most interesting volume entitled "Physic and Physicians: A Medical Sketch Book, Exhibiting the Public and Private Life of the Most Celebrated Men of Former Days, with Memoirs of Eminent Living London Physicians and Surgeons." This work was published anonymously in 1845. It contains much of great interest concerning famous medical men that has not found its way into more formal biographies, and one can see that the writer must have had a vast store of knowledge to draw from. It would be impossible to hold the engaging author to "strict accountability" for all his statements, but they seem to ring true.

"When I was at Padua in 1787," says Dr. Mosley, "I looked for the arms of the great Harvey among the multitude which adorn the public hall of the University, but his were not there. There were several of the English of his standing. It was the custom at Padua for every person who had taken a doctor's degree to have his arms and name hung up in the University when he went away. After such a lapse of time it was not likely that I should obtain any anecdotes concerning him at Padua, but I did not omit to enquire. Among other things on which I could obtain no additional information was the tradition of the extraordinary preservation of his life in the commencement of his journey to Padua, in which there appeared an interposition of something more than human intelligence.

"When Harvey arrived at Dover, with several other young men, in order to embark for the Continent on their way to Italy, they went, with their passports, to Sir Henry Brook, then commanding at Dover Castle. When Harvey presented his passport Sir Henry told him he should not go, but must remain his prisoner. Harvey desired to know the reason and what offence he had committed. The Governor replied that it was his pleasure, and gave him no further satisfaction. In the evening, which was beautifully clear, the packet sailed with Harvey's companions on board. In the night there arose a terrible storm in which the vessel was lost, and all on board perished.

"The next day the melancholy news was brought to Dover. The Governor then explained himself to Harvey, whom he knew only by sight. He told him that on the night before his arrival he had a perfect vision of him in a dream, coming to Dover to cross over to Calais, and that he had a warning to stop him. Great and glorious indeed was the use which Harvey made of a life so miraculously protected!"

Harvey was a great martyr to the gout, and his method of treating himself was as follows: He would sit with his legs bare, even if it were frosty, on the leads of Cochine House, where he lived for some time with his brother Eliah, or put them into a pail of water until he was almost dead with the cold, and then he would betake himself to his stove. He was troubled with insomnia, to cure which he would rise in the night and walk about his chamber in his shirt until he began to shiver, and then he would return to his bed.

Very truly yours,

WILLIAM PIERCE COLES, M.D.

Boston, November 6, 1916.

## APPOINTMENTS.

CORNELL UNIVERSITY.—Dr. Lewis Atterbury Conner, professor of clinical medicine in the Medical College of Cornell University since 1905, has been appointed professor of medicine, in succession to Dr. William Gilman Thompson, who has resigned.

UNIVERSITY OF ILLINOIS.—Dr. Julius H. Hess has been appointed professor of pediatrics and chief of the division of pediatrics in the College of Medicine of the University of Illinois.

UNIVERSITY OF TENNESSEE.—Dr. Frank Maltauer of Cincinnati, Ohio, has been appointed associate professor of bacteriology and public health at the College of Medicine of the University of Tennessee.

HARVARD MEDICAL SCHOOL.—Dr. Leverett D. Bristol, formerly professor of bacteriology and hygiene at the University of North Dakota, has been appointed to the Boston Dispensary Fellowship in public health in the department of preventive medicine at the Harvard Medical School.

UNIVERSITY OF PENNSYLVANIA.—Dr. Joseph McFarland has been appointed professor of pathology; Dr. John C. Heister, professor of anatomy; Dr. George H. Meeker, professor of chemistry; Dr. Horatio C. Wood, Jr., professor of pharmacology and therapeutics; and Dr. Seneca Egbert, professor of hygiene in the medical faculty in the University of Pennsylvania.

## NOTICE.

HARVEY SOCIETY.—The third lecture in the twelfth series before the Harvey Society will be delivered at the New York Academy of Medicine on Saturday evening, November 25, by Dr. Paul A. Lewis, of the Henry Phipps Institute for Tuberculosis, on "Chemotherapy in Tuberculosis."

## RECENT DEATHS.

DR. STERLING BARROWS, a graduate of the College of Physicians and Surgeons, Columbia University, in 1906, died at his home in Worthington, Mass., August 16, 1916, of tuberculosis. He was a Fellow of the Massachusetts Medical Society.

DR. CHARLES EDWIN STONE died of cardio-renal disease at the Lynn Hospital, November 5, 1916, aged 48 years. He was a graduate of the University of Vermont, College of Medicine, in 1906, and had practiced in Lynn. He was a Fellow of the Massachusetts Medical Society.

DR. PERCY GUY DAVIS died at his home in Deerfield, Mass., Oct. 20, 1916, aged 49 years. He was a graduate of the Baltimore Medical College in 1896, and practiced ophthalmology, with an office in Greenfield, Mass. He joined the Massachusetts Medical Society in 1899.

DR. JONATHAN HENRY WOODS died at his home in Brookline, November 16, aged 65 years. He was born in Barre, Mass., was a graduate of the Long Island College Hospital in 1880, and of the College of Physicians and Surgeons, Columbia University, in 1881. He settled in Brookline, and joined the Massachusetts Medical Society in 1882. He was a member of the American Medical Association. His widow survives him.

## SOCIETY NOTICE.

NORFOLK DISTRICT MEDICAL SOCIETY.—A regular meeting of the Society will be held at Masonic Temple, 171 Warren Street, Roxbury, Tuesday, Nov. 28, at 8 p.m.

Business.

Communication, "Milk and Milk Production," illustrated by stereopticon, Reginald W. Bird, Waveney Farms, Framingham, Mass.

Discussion opened by W. W. Howell, M.D.

BRADFORD KENT, M.D., Secretary.

### A CLINICAL STUDY OF THE SECRETIONS OF THE DIGESTIVE TRACT.\*

BY THOMAS R. BROWN, M.D., BALTIMORE.

It might seem almost a work of supererogation to present a paper on digestion in this city—the home of Cannon, through whose brilliant studies we have been led to a real appreciation of the significance of the motor functions of the gastro-intestinal tract. Based on these and other studies, no one can fail to realize that in the interpretation of symptoms and of signs in digestive physiology and pathology, the study of the motor sphere plays the predominant rôle, and, in fact, in many clinics the secretions are not studied at all, the entire attention being devoted to the radioscopic and radiographic study of the digestive tract, as by many it is felt that this is all that is necessary and that the study of gastric, pancreatic and intestinal secretions adds little, if anything, to the appreciation of the underlying pathological process. We feel that this is a very wrong as well as an unfortunate point of view: we believe that these secretory studies not only add to our physiological knowledge in such cases, but furnish data of value both in diagnosis and treatment, and in our paper this evening we shall briefly review our work of the past few years on the digestive secretions, in support of this viewpoint. We shall discuss in turn our studies on (a) the saliva, especially as

regards the relationship between it and the gastric juice, (b) the relation of pepsin and rennin, and of pepsin and hydrochloric acid in the gastric contents, (c) the significance of the absence of hydrochloric acid in the stomach, (d) the study of the soluble proteid contents of the gastric juice in the diagnosis of gastric carcinoma, (e) the gastrogenous diarrheas, (f) the quantitative estimation of the pancreatic ferments in stool and urine, (g) the diagnostic value of the diminution or absence of the pancreatic ferments in the stool, (h) the pancreatic secretion in achylia gastrica, (i) the influence of jaundice upon the pancreatic function, (j) the effect of radium upon the digestive ferments, and (k) ferments of the small intestine. Lack of time will prevent us from discussing other questions of almost equal interest—the gastric secretions in visceroptosis, certain problems associated with hyperchlorhydria, etc.

It would take us much too far afield to discuss the complicated question of the nature of the ferments, their properties, chemical and physical, the nature of their reactions, the question of their specificity, and their reverse action; and yet we must call attention briefly to the latest views held regarding them, as these must be properly understood before one can arrive at a proper interpretation of the findings.

In considering the action of enzymes, certainly the most helpful view is that ferment and substrate occupy the same relationship as toxin and antitoxin, lysin and antilysin, with its specificity of action due to its haptophore group.

The intimate connection between gastric discharge and the flow of bile, pancreatic and duo-

\* Read by invitation at the Peter Bent Brigham Hospital, April 11, 1916.

denal secretions is, of course, well known. We know that vagus impulses cause the initial psychical gastric juice, and also increase pyloric tonus; that the control of the pylorus is fundamentally due to the acid in the gastric contents and that of the first portion of the duodenum—in the former causing opening, in the latter closing—and that the latter seems to be the stronger reflex of the two; we realize that the differential discharge of different foodstuffs is, in the main, explicable upon the rapidity with which the acid reaches the pylorus and duodenum; and that fats inhibit both secretion and pyloric tonus.

Certain facts are not so easy to explain: the rapid discharge of water and of egg-white, the rapid emptying in achylia gastrica, etc. We have shown in dogs the importance of the tonic effect of the fluid in this connection, hypertonic fluids leaving the stomach much more slowly than isosmotic or hypotonic.

As regards the pathological gastric secretion, we know that its absence or diminution is associated with a low degree of pyloric tonus, which accounts for the reflux of duodenal contents in achylia gastrica and after fat feeding. The pancreatic secretion is under both psychic and chemical control, the former easily shown in dogs with pancreatic fistula, secretion beginning from one to one and a half minutes after the ingestion of food, and even after the sight or smell of it, and lasting for from ten to thirty minutes. The alkalinity of the juice not only furnishes a medium suitable for the action of its ferments, but also plays a large rôle in the pyloric reflex.

The important ferments of the pancreas—diastase, lipase, and trypsin-zymogen—are, according to many investigations, secreted in varying amounts, according to the character of the food; other ferments have also been described—a rennin, a haemolysin-zymogen, a nuclease. Bickel has shown that the pancreas is subject to secretory variations analogous to those seen in the stomach, Wohlgenuth the opposing action of the pancreas and the suprarenals, and we the primary stimulating and secondary inhibiting effect of bile upon this secretion. It is conceivable that the pancreatic secretion may be brought about through nervous channels, as Pavlov believes, by the direct action of substances preformed in the food or the products of digestion, or by a hormone, the last being unquestionably the major cause under physiological conditions. This is formed by the conversion of the prosecretin found in the duodenal mucous membrane into secretin by the action of hydrochloric acid, while a similar stimulant action follows the administration of water, fats, and soaps, the two former producing a very faint, the latter a fairly strong secretion, possibly due to another secretin—saprokrinin; while the action of fat is probably reflex, not hormonal.

Probably activated through secretin, and also possibly through nervous channels as well, the

bile also plays an important part in duodenal digestion, not so much from its ferments—as, with a possible faint trace of diastase and of a proteolytic enzyme, it has none—but by its activating influence upon trypsin, diastase, and especially lipase, and its large rôle in aiding the absorption of fats by change in the physical as well as the chemical status of the medium, largely through the influence of bile-salts, which diminish surface tension and dissolve fatty acids, soaps, lecithin, and cholesterol, these bile salts being probably reabsorbed and again acting as stimulants of hepatic secretion. While the secretion of bile seems to be continuous, its elimination is, according to most observers, largely dependent upon the same mechanism as that of the pancreatic and duodenal secretions—secretin.

It is interesting to remember that in the duodenum under physiological conditions the simultaneous presence of the three juices necessary for a complete duodenal digestion is insured, in the main, by the same mechanism, although in the intestinal juice there is also probably a new secretin which may cause renewed flow after absorption. On the other hand, direct mechanical stimulation of the duodenal mucous membrane causes a secretion, while there is the possibility of a psychic and reflex secretion as well. The duodenal juice is alkaline, but less so than the pancreatic secretion.

One has but to mention the ferments present in the duodenal secretion or in the wall of the gut to realize the extreme complexity of the chemical and physical processes carried on here. Besides the prosecretin—not a ferment, of course, but of fundamental importance in the calling forth of ferments—we have erepsin, enterokinase, arginase, nuclease, lipase, maltase, invertase, lactase, a slight trace of diastase from Brunner's glands, a haemolysin, and a glucoside and a cellulose-splitting ferment. The fact that extracts of the wall are much richer in ferment than the juice itself, notably in the case of erepsin and the inverting ferment for the conversion of di- into mono-saccharides, suggests that a considerable part of the ferment action takes place as the substances pass through the wall, the time for which, according to Heidenhain, takes at least several minutes. Of these ferments the most interesting, perhaps, are erepsin, which is also present in many tissues of the body and which accelerates the digestion of the end-products of peptic action, and the enterokinase which converts the inactive trypsinogen into active trypsin.

Prosecretin seems to be present in the whole thickness of the mucous membrane, the enterokinase in much greater abundance in the cells covering the villi. While there is no absolute proof of it, it is probable that the same selective tendencies as regards the character of the food ingested is met with in the duodenal secretion as in the pancreatic flow, with the same possi-

bilities of qualitative and quantitative functional variations.

Certainly, ferments are almost, if not quite specific in action, and in many cases are capable of reversible action, are soluble in water, precipitated by alcohol, absorbed by various substances, such as charcoal, kaolin, etc., have an optimum temperature and an optimum reaction of the medium in which they act, are destroyed by heat, are in some cases met as ferments, in other cases as pro-ferments or zymogens. In their study the greatest accuracy of technique is essential, for extremely slight variations in reaction or temperature of medium may produce enormous variations in the activity of the ferment, and certainly many of the conflicting reports in this field of work are due to a lack of appreciation of this fact.

Perhaps a brief enumeration of the digestive ferments is advisable before reporting our findings in this field. Of the ferments which act upon proteids we meet the pepsin-zymogen of the fundic portion of the stomach, activated by the hydrochloric acid normally present in the gastric content; the rennin found either as ferment or zymogen in gastric juice and to a much less extent in pancreatic and small intestinal juices; the trypsin-zymogen of the pancreas activated by the enterokinase of the small intestine; the erepsin of the pyloric mucosa and of the mucosa and secretion of the intestine, converting peptones into amino acids; the autolytic ferments of the liver and other organs and tissues, the alpha- and beta-proteases of Jacoby, probably of fundamental importance in intermediary metabolism; ferments acting upon the carbohydrates, the diastase of the salivary glands, pancreas and, to a very slight extent, of the small intestine, and the invertase, maltase, and lactase of the intestinal juice and mucosa; the fat-splitting ferment or lipase mostly from the pancreas, but also present in small amount in gastric contents and intestinal juice, and peculiarly activated by the bile salts; and certain other ferments of great interest, although present in but small amount, whose function is not quite so well understood, such as arginase, nuclease, certain ferments acting on the purin bases, and various oxydases, such as aldehydase, tyrosinase, and possibly certain reducing and glucoside-splitting ferments.

Although, according to most observers, the large intestine secretes no enzymes, Wakabayashi and Wohlgenuth claim to have demonstrated erepsin, a peptolytic ferment, and fibrin ferment. One must never forget, also, that not only in the leucocytes, but also in bacteria, many ferments are found which may duplicate the action of the normal enzymes, and also the fact that a similar effect may be produced by various metals in colloid form, which, incidentally, has been utilized in the treatment of malignant neoplasm by the injection of colloid selenium or colloid copper, based mainly upon Wassermann's experiments.

#### (a) *The Relation Between the Salivary and Gastric Secretions.*

We have been especially interested in a group of cases of stomatitis, gingivitis, and glossitis—erosions or superficial ulcerations of gums or tongue or buccal mucous membrane, usually associated with absence of hydrochloric acid in the gastric juice, and singularly resistant to treatment, which by no stretch of the imagination could be regarded as oral manifestations of the two diseases in which sore mouth is so frequently found—sprue and pellagra. With Dr. Freeman, we have studied the saliva in 47 cases to determine whether there was any relationship between the character of the saliva and of the gastric juice, our method being to collect all the saliva produced by the chewing of a piece of rubber of definite size, shape and weight for 20 minutes, always, of course, a long time after the patient had taken food. Our series comprised 10 normal cases, 6 of subacidity, 10 of achylia, or, properly speaking, achlorhydria, 6 of which showed changes in the mouth, tongue, or gums, and only one associated with malignancy, and 15 of hyperacidity or hyperchlorhydria; determining the total amount of saliva, its reaction, and the amount of diastatic ferment. The normal average amount was 22.5 c.c., the average alkalinity, 4, while the diastase ferment, measured by its ability to digest soluble starch, was always present, though showing rather wide variations. The results of our studies showed that as regards quantity of saliva, its reaction and richness in ferment, changes in the gastric secretion have no appreciable effect; in other words, there is no definite relationship between the character of the gastric juice and of the saliva, and, therefore, that it is highly improbable that changes in the saliva play any considerable part in the development of glossitis, gingivitis and stomatitis so frequently met with in cases of gastric achylia. These results were probably to be expected, as month and stomach comprise between them, as it were, a complete secretory apparatus, the former furnishing diastase, the latter, pepsin, rennin, and lipase, and thus are quite analogous to the two secretory apparatuses of a lower level—the pancreas and the small intestine, each with its complete set of ferments to digest all types of foodstuffs. We are now, therefore, determining whether there is any relationship between the saliva and the pancreatic secretion.

Interesting from a physiological point of view was the demonstrated fact that the chewing of bland substances, stimulating neither to the senses of smell nor of taste, produced a flow of saliva quite rich in diastatic ferment,—a view rather opposed to the general physiological opinion. It is also an interesting fact that some of these cases of sore tongue or sore mouth are relieved by the administration of muriatic acid, or pancreatin, or both.

In the very recent studies in this field the ap-

proach has usually been from the other side, that is, the influence of the saliva upon the gastric secretion. Sticker showed that deficient salivary activity is followed by arrest or diminution of the hydrochloric acid secretion, while Biernacki and Schard showed that it was not the saliva *per se*, but its combination with food, that stimulated gastric secretion. We did not study the peptolytic ferment or substance of the saliva which is capable of splitting glycytryptophan.

(b) *The Relation of Pepsin and Rennin, and Pepsin and Hydrochloric Acid.*

There has been much discussion as to whether pepsin and rennin are separate ferments or are identical. Pawlow and many of his followers holding that they are identical; Heidenhain and perhaps the majority of workers believing that they are separate and distinct ferments, the more recent work of Rüttimeyer, Einhorn and Laporte agreeing with this latter view. Of course, there are many arguments in favor of their being different, as, for example, that pepsin acts only in acid, rennin in acid, neutral or slightly alkaline media, and the variation in the viability of the two ferments. Dr. Schnack has carried on under our direction a series of experiments in this connection, estimating pepsin by the Mett method, rennin by the Boas procedure, hydrochloric acid by the use of Toepfer's reagent, and the total acid with phenolphthalein as indicator in a series of 51 cases, the gastric contents being either that aspirated after the ordinary Ewald test meal, or from the fasting stomach. These studies show beyond question that although, as one would expect, the pepsin and rennin content are parallel in most cases, nevertheless there are so many exceptions to this as to prove clearly that the production of one enzyme may be suppressed or increased without affecting the production of the other; in other words, demonstrating that pepsin and rennin are separate enzymes.

Incidentally these studies also show that there is no relationship between the amount of pepsin and of the free hydrochloric acid or the total acid content,—a fact we have also demonstrated in many cases of achylia as well as hyperacidity, in which cases we have employed the edestin method for the estimation of pepsin in preference to the Mett method. We have always felt that the hydrochloric acid as secreted in the stomach is always of constant percentage, but that the pepsin richness may vary.

(c) *The Significance of the Absence of Hydrochloric Acid in the Gastric Contents.*

We realize that the term achylia gastrica is very loosely used, for, as we noted before, although of a large series of cases studied by us that showed no hydrochloric acid, in the majority the pepsin was absent, in some it was present even in normal amount. Roughly speaking, we use the term to mean no hydrochloric acid in

the gastric contents after the ordinary test meal with a total acidity under 12 or 15, and with a hydrochloric acid deficit, although Rehfuess by his fractional methods of study insists that in some of these cases free hydrochloric acid may appear in the gastric contents long after the usual time of extraction of the meal. It was not many years ago that the absence of hydrochloric acid was considered, if not diagnostic, at least extremely suggestive of gastric carcinoma. To realize the error in this point of view and to show that in the vast majority of cases achylia is associated with benign conditions, one has but to mention its presence in a large series of cases. Let us briefly enumerate some of the diseases in which it is frequently found, drawing only from our own cases. We must realize, of course, that it may represent the late stage of an inflammatory process, or an atrophy of the mucous membrane, or a lack of functional activity of the glands, either due to a pure neurosis, to psychic disturbances, to a toxæmia, or to a reflex inhibition from elsewhere, as, for example, the achylia frequently met with during menstruation.

The conditions in which we have met with an absence of hydrochloric acid with peculiar frequency or of especial interest are:

1. The last stages of a chronic gastritis.
2. Gout and arthritis deformans, or perhaps better called chronic infections arthritis, leading in the first case to the substitution of an acid for an alkaline therapy, and in the latter to the belief held by many in the intestinal origin of the disease.
3. Various infectious diseases—tuberculosis where it is often found, and typhoid fever, in the latter of which in a number of cases we have found a complete achylia following the disease, which may be one of the causes of the gastrointestinal symptoms often met with, which is probably toxic in origin and not due to destructive changes in the glands, as in many cases after a considerable period of time, in several of our cases more than a year, there was a gradual return to normal gastric juice, and in all these cases the use of hydrochloric acid therapeutically should be advised; sinusitis, pyorrhoea alveolaris—a very frequent cause, probably leading to a true infectious gastritis and being the most potent factor in the gastric dyspepsia and diarrhoea in older people—and tonsillitis.
4. Various intestinal parasitic diseases, especially infection with the uncinaria,—hook-worm disease,—though frequently found in infections with tapeworm, round worm and entamoeba.
5. Conditions associated with chronic passive congestion, notably chronic nephritis and myocardial disease.
6. Pernicious anaemia, a group of peculiar interest because of the resemblance of the symptoms to gastric cancer, and because of the view

held by some that the anaemia is secondary, the gastro-intestinal condition primary.

7. Pellagra and sprue—in the latter associated frequently with a concomitant absence of pancreatic secretion, and in each disease a marked improvement of the digestive symptoms often following the administration of hydrochloric acid, in association with pancreatic ferment in the case of sprue.

8. Cancer, not only of the stomach but often of other organs even outside the abdominal cavity, especially in the late stages of the disease.

9. Diseases of the thyroid, and here both in Graves' disease or hyperthyreosis, and myxoedema or hypothyreosis it is often found and is probably the cause of the marked diarrhoea which may be the only symptom of the former disease.

10. Linitis plastica, or cirrhosis of the stomach, probably representing in most cases the conversion of an old ulcer into a malignant condition with marked hyperplasia of the fibrous tissue and very little cellular participation.

11. High grades of ptosis and atony of the stomach, although here hyperacidity or normal acidity may also be found.

12. Chronic gall-bladder disease with and without jaundice where we have found it in a very considerable proportion of cases, and where it may prove of real aid in diagnosis.

13. After sudden shock, violent emotions, worry and overwork.

Truly a large group of cases and very interesting, as it makes one realize under what various stimuli—infectious, toxic, nervous, etc.—the condition may develop, and how difficult it may be to differentiate the true underlying condition. Unlike many others we have not found the presence of pepsin in large amount of much value in differentiating the purely functional from the organic achlorhydrias, for in a large series in which the pepsin was estimated quantitatively by the edestin method we found in the great majority of cases, both functional and organic, the practical disappearance of pepsin *pari passu* with that of the hydrochloric acid. As to the effect of the absence of hydrochloric acid this is very varied, and in many cases difficult to explain, as, for example, the fact that in certain cases it is associated with a diarrhoea, in others with constipation, and in still others with a normal bowel habit. After all, to appreciate what the absence of hydrochloric acid may bring about we must always keep in mind its multiplex functions—its action upon the pyloric sphincter; its rôle in converting the inactive prosecretin into the active hormone of the pancreas, secretin; its disinfecting properties; its rôle in the digestion of the proteins; the essential part it plays with pepsin in the digestion of connective tissue, and its activating power upon the zymogens of pepsin and rennin.

(d) *The Study of the Soluble Proteid Contents of the Gastric Juice in the Diagnosis of Gastric Carcinoma.*

Boas said a few years ago "attempts to make an early diagnosis of cancer of the stomach are useless—we should be satisfied to make a correct late diagnosis." Perhaps our x-ray brethren will not agree to this, but with a few brilliant exceptions we feel that this dictum is still unquestionably true. Correct diagnosis of late cancer is often very difficult if we have not a palpable tumor, and if we realize, on the one hand, how in a large proportion of cases the growth originates behind the left costal arch on the lesser curvature and is not palpable until a considerable portion of the stomach is involved, and, on the other hand, the very slight diagnostic significance of the lack of hydrochloric acid and even of the presence of lactic acid and of the Oppler Boas bacilli, the diagnostic difficulties are very apparent. Most of these special tests are based on the assumption that the cancer cell in its growth or in its disintegration develops a proteolytic ferment which carries the cleavage of the proteid molecule further than normally met with in gastric digestion. Some of these tests have proven singularly disappointing, as the glycyltryptophan test, for we now know that the saliva contains a substance, possibly an enzyme, which can also split up this substance, while the more complicated tests of Saxl and Salomon, and especially of Salkowski—the increase of the colloidal nitrogen in the urine in gastric cancer—are not only too difficult for ordinary clinical study, but, according to our experience, have proven singularly unreliable, far more so than the strictly biological tests, such as the increase of the antitrypsin in the blood. We have for the last few years been much interested in the simple method devised by Wolff and Junghans for determining the amount of soluble proteid in the gastric juice by adding a solution of phosphotungstic acid to graded dilutions of filtered gastric juice, a significant increase being suggestive of gastric carcinoma. The test, however, is obviously only applicable to those cases with no free hydrochloric acid, and is, therefore, not of value in the early diagnosis of the disease. From tests made upon over 200 cases of benign and malignant achlorhydrias in which one could judge with a fair degree of success the correctness or incorrectness of diagnosis either by the operative findings or by the subsequent course of the case, in over 85% the tests gave a correct interpretation of the condition—a large enough percentage to warrant its use as a routine procedure in all doubtful gastric cases associated with achlorhydria, and agreeing in practically all details with the results of Smithies' much larger series from the Mayo Clinic.

(e) *Gastrogenous Diarrhoea.*

No more interesting group of digestive cases can be found than that of the gastrogenous diarrhoeas, that is, cases of diarrhoea associated with a complete lack of hydrochloric acid in the gastric secretion. It is extremely difficult to determine why some of these cases of achylia are associated with diarrhoea, others not, for in all cases the food must enter the intestines in an unprepared form, in all the bacteria-content of the stomach and upper intestines must be higher and in all the pylorus tends to remain open; and yet the result of therapy and the study of the stool demonstrate that these cases are not purely intestinal in origin. We have been especially interested in this group in determining by the method to be mentioned later whether or no the diarrhoea was due to an associated disturbance of pancreatic function, but a careful quantitative estimation of the pancreatic ferments in cases of achylia, with and without diarrhoea, showed that this is not so (as suggested by Gross of Vienna, but opposed by Ehrmann of Berlin), and, therefore, some other mechanism must come into play. Perhaps in these cases the hydrochloric acid acts as one link in a chain,—a link to be used over and over again in the production of a hormone which has as its object the inhibition of the motor function of the intestine; for the reaction is not a quantitative one, small doses of hydrochloric being quite as effective as large. There is really no more brilliant therapy than the treatment of these gastrogenous diarrhoeas with small doses of hydrochloric acid—to see the symptoms in a case with intractable diarrhoea of years' duration, often of the morning type, disappear with return to a normal stool habit after a few doses of the acid, is almost incredible; and yet this happens in most cases, although obviously to get permanent results the acid must be administered regularly and sometimes indefinitely. Unquestionably certain of the diarrhoeas met with in pernicious anaemia, nephritis, tuberculosis, typhoid fever and its convalescent period, pellagra, sprue, and various neuroses are of this type, and often are markedly helped by acid therapy.

(f) *The Quantitative Estimation of the Pancreatic Ferments in Stool and Urine.*

Pawlow and his followers have shown in dogs the definite quantitative response of the pancreatic secretion to food stimuli, while Wohlgemuth and others believe that they can also demonstrate a qualitative response at least as regards the carbohydrates. Although incapable of absolute experimental proof it is highly probable that similar conditions exist in man, that is, that there is a definite relationship between the amount and possibly the type of food ingested, and the amount and character of the pancreatic response. Of course, if such conclusions are

true, it is essential for clinical purposes that a normal be established.

We have studied quantitatively the diastase in the feces in the hope that by establishing the normal limit, especially the low normal, we might have criteria of value in the diagnosis of organic or functional diseases of the pancreas, determining whether or no in such diseases a definite variation from the normal is constantly found. We have chosen the diastase in preference to the trypsin or lipase because of its greater stability, because of the marked proteolytic action of the bacteria, much more striking than their diastatic action, because practically all the diastase that is secreted into the intestinal tract arises from the pancreas, the amount from Brunner's glands and gall-bladder, the only other sources, in all probability being practically negligible and because it is a preformed ferment and does not require an activator.

We have attempted to devise a method which is simple, practical and exact, and based on physiological principles, and by applying the same method to normal and pathological conditions to draw comparisons of value in diagnosis. In practically all the diseased conditions the diagnosis was verified by operation.

Of course, a great many methods have been suggested as qualitative and a few as quantitative tests of the pancreatic function—Sahl's glutoid capsule, Müller and Schlecht's gelodurot capsule, the study of the stool for large amounts of meat and fat (creatorrhoea and stercorrhoea) after the Schmidt diet, the Volhard method of obtaining the duodenal contents from the stomach by administering olive oil by mouth and the examination of the fluid for the pancreatic ferments, Ehrmann's palmitin test, Einhorn's intubation of the duodenum, A. Schmidt's nuclei test, the Cannidge reaction, and the alimentary glycosuria test. None of these is definitely quantitative, however, and for this purpose the estimation of the pancreatic ferment in the stool suggests itself. Of these ferments the trypsin and lipase are more easily destroyed by bacteria, each requires activation to show its maximum efficiency, the former by enterokinase, the latter by bile; and the proteolytic action of the intestinal bacteria may complicate the findings very markedly.

Of course, in all such estimations the salivary diastase—identical in action with that from the pancreas—must be eliminated, but this is easily done by administering a food in liquid form in which the act of chewing is not called into play. Of the other ferments found in the small intestines—crepsin, peptolytic ferment, nuclease, lipase, fibrin ferment, hemolysin and glucoside-splitting ferment—none appreciably affects the action of the diastase. This action, of course, is the conversion of starch to maltose, the intermediary products being soluble starch, erythro-dextrin, achrodextrin, and isomaltose.

As for the methods described for studying the diastase in the stool to determine the pan-

creatic function, most are based on the same principle,—the conversion of starch into lower products which do not give the characteristic starch reaction with iodine or the determination of the sugar produced by this cleavage by Fehling's solution or some other reagent. Roberts, Strasburger, Wohlgenuth and Ed. Müller—all describe such methods; the results, however, are open to serious criticism because they used different foods and various or no laxatives, and thus rendered possible enormous variations in the diastase content of the stool. Diarrhoea always increases the stool diastase, constipation lessens it, while Ury has shown that of the purgatives, senna really increases the secretion of diastase, while the bitter waters and bitter salts have no such effect. It would seem wise, therefore, to choose a bitter salt as a laxative of choice in these investigations. Enriquez, Ambard, Binet and Durand reported a number of cases in which the digestion of starch was measured by the quantitative estimation of the sugar formed. We, however, regard the Wohlgenuth test for diastase as far more practical than the quantitative estimation of the sugar formed, and quite as free from criticism on theoretical grounds. No discussion of the ferment content of the stool would be complete without a reference to the very extensive and interesting studies of Crohn in this direction. In the case of both duodenal fluid and stool he gives a table of normal variations for the three ferments,—lipase, trypsin, and diastase,—and of these three, he believes trypsin is the most constant. He believes that the method lends itself to prognosticating qualitative and quantitative variations in the strength of the pancreatic external secretion.

In the methods employed by us in determining the normal amount of diastase in the stool, we have tried to eliminate as far as possible all sources of error, and so to standardize the different steps that mistakes would be reduced to a minimum. The patient is given a high enema the night before, the evening meal being a very light one. At 7 A.M. the next day, 750 cc. of milk is given, at 7.30 A.M. and again at 8 A.M. 1-2 an ounce of Epsom salts ( $Mg SO_4$ ), and at 8.30 A.M. a glass of water containing 1-4 of a teaspoonful of bicarbonate of soda. All the stool up to 2 P.M. is saved in a vessel containing two ounces of toluol, and kept on the ice or in a cool room. If less than 400 grammes or cubic centimeters of stool are obtained, an enema of a pint of water is given, as in our experience between 400 and 1100 cc. of stool is the amount to be expected in the individual case.

Barring the inevitable possible mistakes always associated with the gathering of specimens, the possible sources of error are psychic variations in the different patients, differences in their intestinal bacterial flora and variations in the motor functions of their stomach and intestines, but we believe these inevitable sources of

error are reduced to a minimum by the method employed.

Of course, the condition of the salts in the stool has also a distinct effect in activating or depressing the diastatic action, but we do not believe that if our technic is strictly followed out it is necessary to dialyze the stool and make our studies from the desiccated specimen.

Preservation of the specimen in a very cold place or on the ice, and the immediate examination of it after the entire specimen has been obtained, is imperative because of the marked effect of variations in temperature upon the ferment, and also because by allowing it to stand we are introducing two variable factors—changes in the ferment due to temperature and chemical changes in the medium and the influence of the varying bacterial flora upon the ferment; and, secondly, the diastatic action of the bacteria themselves. We believe that the wide variation obtained in certain of the investigations is dependent upon the lack of insistence upon certain of these points, and that with a rigorous technic figures as to normal limits are of real value.

From our study on the diastase content, and to a less extent upon the trypsin, of the stool in normal conditions we feel justified in concluding that the stool, if a rigorously exact method is carried out, furnishes a ferment content within definite limits (600 units being the low reading of 20 normal patients in the case of diastase).

While, of course, realizing that this method is not especially esthetic, nevertheless we feel that it is more truly quantitative than the study of the duodenal contents, for in the latter case, there are far too many variable factors, especially the difference in the time the bucket enters the duodenum, and the consequent difficulty of determining at what phase of pancreatic digestion the fluid is obtained, and the varying admixtures of bile and duodenal secretion.

We have also estimated the diastase of the urine in normal and certain pathological conditions, the total amount in the 24 hours varying in health from 15 to 120 units. As to the value of the estimation of the urinary diastase diagnostically, the study of a number of cases of pancreatic and renal diseases has made us feel that the two main reasons why it is not diagnostic of pancreatic disease are, first, because of the widespread distribution of this ferment in the body and the possibility of a vicarious increased activity of other sources of supply in the case of pancreatic disease; and, second, because in various renal diseases there is usually a marked lessening of urinary diastase due to deficient renal permeability. For these reasons, while a persistently low diastase content of the urine if the kidneys are normal is suggestive of pancreatic disturbance, yet the normal figures in our series should prove of far more value in the study of the renal function.

(g) *Diagnostic Value of the Quantitative Study of the Pancreatic Ferments in the Stool.*

Recently we have been standardizing the tryptic ferment also in the stool, although for various reasons it is not so satisfactory as the diastase, especially because it is secreted as a zymogen, and because the end reaction is marked by a white precipitate instead of a sharp color change; nevertheless, so far the findings have usually harmonized with those obtained in the study of the other ferment. In regard to lipase our results have not been satisfactory, possibly due to the fragility of the ferment and the enormous variability of its action due to the varying bile-content of the stool. We have used our method especially in the study of carcinoma of the pancreas and chronic pancreatitis. In the case of the former, carcinoma of the pancreas, we have made the diagnosis in ten cases, subsequently verified by operation or by autopsy, some with jaundice and some without; and the diagnosis was correct in all the cases. In each case there was still no evidence of starch digestion in the tube of least dilution corresponding to twelve grammes units (600 units being low normal), lower dilutions not being studied as we felt that the limit of error had been reached and that we could say that there was practically no diastase in the stool. Enriquez, Ambard and Binet found no diastase in two cases of cancer of the head of the pancreas, verified by autopsy, and Durand none in one case probably malignant.

The only stool in all our studies, except those of carcinoma of the pancreas, in which we found a complete absence of pancreatic ferments was from a typical case of sprue of more than a year's duration, and in this case no one factor played such a large rôle in the symptomatic cure as the administration of pancreatin by mouth, although even now when the patient is clinically well, and has gained over 50 pounds in weight, a return of the diarrhoea may be brought about by withholding the pancreatin for a few days, and the stool studies still show that normal pancreatic ferments are wanting.

Although we have had no such case in our series we should always remember one other condition in which no pancreatic ferments are found in the stool—complete closure of the pancreatic duct or ducts by stone, etc.; in these cases, if the condition is acute, we usually find a marked increase of diastase in the urine.

We have found a diminution but not absence of diastase and trypsin in 11 cases of pancreatitis (true pancreatic cirrhosis as verified by operation), in chronic gall-bladder disease associated with jaundice, and in chronic infectious or wasting diseases of long duration. Ehrmann reported a case of chronic pancreatitis with marked diminution of diastase in the stool, and Durand 3 similar cases. It would thus seem, that in cases of chronic pancreatitis pancreatic

ferments while present in the stool are markedly diminished.

We feel, therefore, that if all the controllable factors are standardized, the study of the diastase and trypsin content of the stool should be of real value in the diagnosis of pancreatic disease, especially carcinoma.

(h) *Pancreatic Secretion in Achylia Gastrica.*

According to Starling, "the formation of hormones and their circulation through the blood to the reactive tissue suffices to account for the whole activity of the pancreas, and it is doubtful whether in this activity the nervous system plays any part whatsoever"; this hormone, secretin, of course, being produced by the action of the hydrochloric acid of the gastric contents upon the prosecretin of the duodenal mucous membrane. If this were so, there should be practically no pancreatic ferment secreted in true cases of achylia gastrica, for the accessory rôle in stimulating pancreatic secretion played by water, fats, fatty acids, soaps, peptones, alcohol, sodium chloride, lipoids, and lecithin is minimal. To see whether or not this is so,—in other words, to test Starling's view,—we have made very careful quantitative estimations of the diastase and in some instances of the trypsin in the stool in 7 cases of true benign achylia gastrica, for if it is the action of the free hydrochloric acid upon the duodenal mucous membrane which practically alone calls forth the secretin of the pancreas by converting prosecretin into secretin, then in those cases without hydrochloric acid in gastric contents there should be a marked diminution of pancreatic secretion. In three of these cases, there was a persistent diarrhoea of long standing—a true gastrogenous diarrhoea, while in the other 4 cases the bowels were normal or costive. Our findings were that there was absolutely no diminution in 6 of the 7 cases, while in one case only were the ferments diminished, and then very slightly, thus showing that in the absence of hydrochloric acid some other mechanism is employed to call forth pancreatic activity,—a view also held by Ehrmann from his qualitative studies of the duodenal contents obtained by aspiration of the stomach after oil feeding. After all, the well-known fact that there is a psychic secretion of pancreatic juice, and the numerous observations of Pawlow and others would make one feel, as our results also show, that in pathological conditions at least, and possibly also normally, if the results of Pawlow's and Fleig's experiments are properly interpreted, there is a nervous as well as a humoral method of pancreatic secretion.

(i) *The Influence of Jaundice upon the Pancreatic Secretion.*

We have neither time nor space more than to touch upon certain other findings of interest in the study of the digestive ferments. In study-

ing the effect of jaundice, artificially produced in dogs, upon the pancreatic secretion we arrived at the following conclusions: first, after the ligation of the gall duct and the consequent production of a rapidly developing jaundice there is a marked reversal in the pancreatic juice both as regards amount and ferment richness after the different types of foods; there is more juice with milk than with meat, and where before the trypsin or the diastase showed a definite increase, now a decrease is likely to be met with, and vice versa; and, second, the removal of the bile from the intestine after the previous withdrawal of the major portion of the pancreatic secretion produces in a very short time a rapid loss of weight and strength, ending in sudden death, and emphasizes anew the great importance of the bile as a partial substitute for the pancreatic secretion if the latter is absent or markedly diminished. On the other hand, different conditions obtain in chronic jaundice, and here we find, as we have shown in many cases in human beings, a marked lessening of hydrochloric acid and pepsin in gastric contents, and of diastase and trypsin in the pancreatic secretion. The effect of acute jaundice upon the pepsin curve of secretion has been shown by Glube as similar to our pancreatic ferment curves.

(j) *The Effect of Radium upon the Digestive Ferments.*

A few years ago when radium and radio-active waters were suggested as cures for many and varied ills, it seemed of interest to study the effect of the emanations upon the digestive ferments. In our first series of experiments we used radio-active substances from various sources, such as radium lead and radio-active ores, while in our second series, carried on several years later with our assistant, Dr. Hendry, we used extremely radio-active water artificially prepared and kindly furnished us by Dr. Burnam from Dr. Kelly's supply. In our first series of experiments the influence of the radio-active substances was extremely slight, and our conclusions were that none of the radium preparations seemed to have any effect upon the autolytic ferment of the liver, although this ferment was activated by lead chloride solution; with diastase the very radio-active D.E.F. possessed an inhibiting effect, while the radium D from emanations had a slight stimulating effect, increasing with the length of time and the amount of fluid used, this ferment being also markedly activated by various salts; with pepsin we found a slight inhibiting effect more marked with the very radio-active D.E.F. although slight in comparison with the inhibiting effect of saturated lead chloride solution.

In our second series of experiments on pepsin, trypsin, lipase and diastase the only effect noted was a very slight inhibition in a very few cases; in the majority of cases no effect whatsoever;

our findings thus agreeing with the more recent work of Gudzent and Stoklasa, and in direct disagreement with the earlier work of Bickel, Bergel, Wohlgemuth, and others, who reported a marked activating influence upon various ferments, including the autolytic ferments of the liver, diastase, trypsin, pepsin and glycolytic ferment.

Certain incidental findings were of interest in these studies of ours, as, for example, the remarkable influence of the reaction and of the salt content of the fluid, and the peculiarly stimulating effect of certain inorganic salts, notably, of lead chloride upon that most interesting of ferments,—the autolytic ferment of the liver, first described in 1876 by Salkowski, of great importance in the intermediary metabolism of proteins; verified by Neumeister, Magnus-Levy, and Jacoby, and, according to the last investigator, consisting of two ferments, an alpha- and a beta-protease. This finding suggests a possible explanation for the action of the so-called alteratives, potassium iodide, etc.

(k) *Ferments of the Small Intestine.*

We have done practically no work upon the numerous and interesting ferments of the small intestines—lipase, diastase (in minimal amount), maltase, lactase, invertase, enterokinase, erepsin, arginase, nuclease, rennin, mucinase, and the various oxydases and reductases described by some, except in an occasional case to verify Ury's findings,—that after certain of the laxatives and purgatives, notably senna, they are considerably increased; but we feel sure that, notwithstanding the difficulties met with, these ferments furnish a very fertile field for study in the hope of elucidating many of the complex problems of intestinal digestion, with the probability of a definite differentiation of a number of quite separate conditions now loosely grouped together under the vague term of intestinal indigestion.

*Conclusions.*

In this short paper we have attempted to present, although of necessity briefly and incompletely, the results of some of our studies upon the secretions of the digestive tract—studies carried on in the main in the interspaces of a busy clinical life,—laboratory cases, as it were, in the desert of practice; and from this presentation we trust that we have shown that the neglect of the study of the secretory side is most unwise if we wish to have a broad conception of the diseased process in many and varied interesting digestive conditions. From these studies it seems justifiable to draw certain conclusions, some of purely physiological, others of clinical interest. Of the former the most interesting were the demonstration of the lack of influence of the gastric secretion upon the character of the saliva; the fact that a saliva rich in diastatic ferment is secreted during the chewing of most substances, stimulating neither to the

senses of taste nor smell; the independence of rennin and pepsin, the lack of definite quantitative relationship between the pepsin and the hydrochloric acid of the digestive juice, and the proof that in the absence of the normal mechanism of pancreatic stimulation some other mode of calling forth the ferment of this gland, probably nervous in character, is called into play.

From the clinical side, although also of physiological interest, the conclusions which seemed to us to be of interest are the large number of conditions in which an absence of hydrochloric acid in the gastric juice is met, and the importance of the appreciation of this fact both diagnostically and therapeutically; the significance of an increase in the soluble proteid of the gastric contents in the diagnosis of gastric carcinoma; the importance of recognizing the group of gastrogenous diarrhoeas, and the brilliancy of their treatment with hydrochloric acid; the fact that with a rigorous technic there are low normal limits to the quantity of diastase found in the stool, and that an absence of these ferments is very suggestive of cancer of the pancreas.

Thus, although never losing sight of the greater importance of the motor sphere in digestive pathology, and recognizing that the appreciation of motor disturbances is absolutely essential both as regards diagnosis and therapy, nevertheless we feel and also trust that we have shown, that the study of the digestive secretions is not without value; that from it we obtain an insight into the physiology and pathology of digestion not obtainable from motor studies alone; that without this study, many of the most interesting problems in the digestive sphere would remain unsolved or misinterpreted, and that, therefore, it is both unscientific and short-sighted to eliminate from our diagnostic methods the study of the secretions of the digestive tract.

## PSYCHIC AND NEUROPSYCHIC AFFECTIONS IN WAR.\*

By E. RÉGIS, M.D., BORDEAUX, FRANCE.

*Professor of Psychiatry in the Medical Faculty of Bordeaux, Physician-in-Chief of the Second Territorial Class.*

[From the Central Psychiatric Service of the Military Hospital at Bordeaux, France.]

It is only since the South African War, and especially since the Russo-Japanese War, that the psychoses and neuropsychoses of war have begun to be recognized and studied.

Among the principal points emphasized by the Russian psychiatrists, such as Jacoby,

Chaikewitch, Serge Soukhanoff, Oreretzkowsky, Vladitchke, Ermakoff, Antokratow, and Cygietrejech, or by the English, such as Stewart and Kay, may be cited: First, the great frequency in modern wars of cases of psychoses and psychoneuroses,—a frequency such that the Russians had to establish at Kharbine and at Moukden, in Manchuria, psychiatric hospitals. Second, the predominance of acute, often transitory, psychoses and neuropsychoses clinically analogous to those resulting from severe accidents. Third, the particular multiplicity of cases of this sort following maritime battles. Fourth, the necessity of psychiatric care for armies on campaign, consisting of improvised hospitals in regions sufficiently remote from the base of operations and from the passage of troops.

The facts revealed by the Russo-Japanese War did not attract sufficient attention. I had, nevertheless, endeavored in my teaching of military psychiatry, and in the latest three editions of my text-book, to point out their nosologic and practical importance.

From the nosologic point of view, I insisted, with Jacoby, on this fundamental characteristic, namely, that "modern land and naval battles by the suddenness, extent and horror of their ravages, act more and more in the manner of cosmic catastrophes, such as earthquakes, which may determine genuine epidemics of psychic disturbance. As in great collective disasters, in fact, one sees terrified and distracted soldiers fleeing automatically, disoriented, unconscious, sometimes hallucinated, no longer knowing what they are about, a prey to those new forms of disease akin to the traumatic and hysterical neuroses of industrial origin." In confirmation, two of my pupils, Laurès and Hesnard, published interesting observations establishing the fact that the psychoses, following the explosions of the *Jena* and the *Liberty*, had manifested themselves especially under the form of mental confusion, or of hysteropathic mental accidents. From the practical point of view, I had insisted, equally with Jacoby, on the organization of a special psychiatric service in case of war. "This is a first step in the course of the psychiatric assistance of armies on campaign. We must hope that the question will not rest there, and that the example given by Russia will be followed by all nations, today especially, when the European people are exposed to very severe and protracted wars.

"The solution adopted by Russia, of special hospitals for the insane improvised at sufficient distances from the field of operations, is certainly the best. In case of need, even special pavilions annexed to ordinary field hospitals would suffice, on condition that their medical direction was entrusted to specialists. The psychoneuroses or psychoses from moral shock, which predominate in great cataclysms and great battles are, in fact, in the large majority of cases, essentially acute, transitory, and curable in a few days. On the other hand, no treat-

\* This article represents a translation of fragments from an original and hitherto unpublished manuscript prepared by the author in November, 1914, as a report to the French Minister of War from the Psychiatric Clinic of the Military Hospital at Bordeaux, France.

ment is better suited to the acute psychoses of all forms than rest in bed. One might, therefore, I repeat, in default of special hospitals, attach pavilions for the insane to the ordinary field hospitals. These pavilions would serve at the same time for the traumatic insane and for the post-operative, who would evidently be more numerous in the circumstances of which we speak.

"It is an organization of this sort which Professor Simonin of Val de Grâce also recently urged in his conference of December 13, 1912, with the federal union of reserve and territorial physicians, on psychoses of wartime and psychiatric aid in the field."

Real war broke out before the psychiatric aid which we had been urging for nine years had yet been organized. I cannot say whether the English, Russian, German and Austrian psychiatrists with whom my colleague Taetzel and I had discussed this question of military psychoses at the International Congress on the Treatment of Insanity, at Berlin, in 1910, have practically solved this problem, or in what way. It would be of importance to know this, for already, in recognized works, military physicians, such as Stier of Berlin, Drastich of Vienna and Kay of Bristol, had insisted on the treatment of mental diseases during the war.

Be that as it may, from the beginning of hostilities in August, 1914, Dr. Pouchet, director of the health service of the eighteenth district, understanding the necessity of doing something in this regard, established the care of cases of psychoses and psychoneuroses among soldiers in a central psychiatric service, supplied by patients coming from other sanitary organizations of the district, who were informed by circular. This central service is located at the military hospital at Bordeaux, directed by my colleague and friend, Dr. Salesses.

The cases which I have observed up to this day, December 31, 1914, to the number of 150, may be divided into two principal categories. First, the cases of psychoses in soldiers who have not been under fire,—ordinary, common psychoses, merely supervening on the occasion of war (disequilibrations, degenerations, alcoholism, general paralysis). Second, psychic and neuropsychic affections in soldiers returning from the front and induced directly by battle. Of the former group there were 62 cases, of the latter 88. It is this latter group of cases which I wish to examine briefly in the present study.

#### I. PSYCHIC AND NEUROPSYCHIC DISTURBANCES IN BATTLE.

Of 88 cases of psychic and neuropsychic disturbances in battle which I have hitherto observed, 50 are properly psychic and 38 neuropsychic.

##### PSYCHIC DISTURBANCES.

Traumatic psychic disturbances, whether proceeding from a moral, purely emotional trauma-

tism or from a physical traumatism, are represented essentially by symptoms of mental confusion with or without hallucinatory oneirism, that is to say, by the exact symptoms which characterize the psychoses of intoxication and of infection.

This opinion, which is in accord with the facts observed by the Russian psychiatrists in Manchuria, and with those resulting from the explosion of the cruisers *Jena* and *Liberty*, or from the recent earthquakes in Sicily, is again confirmed by the facts of actual war, in which the two principal psychic disturbances established by us have been, hallucinatory oneirism and mental confusion.

#### Hallucinatory Oneirism.

Hallucinatory oneirism has never been lacking in the 88 cases affected with psychic or neuropsychic disturbances following battle. In this regard, I may remark that there are very few wounded returning from battle who do not dream more or less of the fighting. I have questioned a large number at random and the majority, even those whose sleep was absolutely calm before, have declared that on their return from the front, and for several nights at least, they have had dreams of this sort. This is very natural and need occasion no surprise, but it is not a question of ordinary dreams without pathologic character. The morbid dream, which alone constitutes oneirism, begins only when it imposes itself as a reality,—when the sleeper really lives it,—and this oneirism, which we see participates in the second stage of hypnosis, may, like it, pass from the dumb dream to the dream in action. It is of this living dream, this hallucinatory oneirism only, which I wish to speak.

It has never, I have said, been absent in our patients with psychic and neuropsychic disturbances. The events and incidents of the battle which serve as its theme are variable. There is the bursting of shells, the shrapnel, the fusillades, the charges, the evolutions of the aeroplanes, the life in the trenches, the spectacle of the wounded and of the dead. Sometimes the scenes are multiple in the same patient, and this is most frequently the case. At other times the scene is single, always the same, and it consists then in a habit of painfully living over again the terrifying circumstances of the wound or of the emotion of shock.

The degree of hallucinatory oneirism varies equally among its subjects. Sometimes the vision is simply painful and transitory. Sometimes it seizes the sleeper to such degree that he literally lives it and it continues even into the day in what has been properly called a prolonged dream. Several of our patients of this grade wave their arms, seem agitated, and talk in their dreams, allowing significant exclamations to escape.

If the intensity of this hallucinatory oneirism marks the profound influence of the emotions

of a battle on soldiers, it contributes, for its own part, by a sort of delayed shock, to maintain in a high degree the impressionability of its subjects. Happily its action is only temporary, the duration of the hallucinatory oneirism itself being but transitory. I have rarely seen it last more than two weeks, even in the most acute cases. Ordinarily it disappears at the end of several days, after which, sleep again becomes calm and restorative.

Under the circumstances and conditions of examination it has been impossible for me to verify here the clinical law of the relation between the urine curve and the oneiric curve which we have previously established, but in various instances I have been able to establish the diminution of the total amount of urine in patients at the acme of the oneirism and its augmentation continuing to the crisis, to the moment of the disappearance of the psychic disturbance.

I think I have no need to add that the hallucinatory oneirism of soldiers returning from fire has nothing to do with ethylism. All my patients, or practically all, were absolutely sober. I think, moreover, I have made due allowance for this error, too long a time having elapsed for painful, terrifying occupational nocturnal hallucinations to be the characteristic index of alcoholic intoxication. In reality, they may manifest themselves exactly thus in any metabolic disturbance of the organism, produced either by an intoxication or by any sort of infection, or, what seems equivalent, by an emotional shock.

An interesting fact in this regard is that since the declaration of war, hallucinatory oneirisms of battle have appeared, not only among soldiers who have actually been present at combats, but also among alcoholics, whether soldiers or not, who have remained at their homes or in garrisons. A territorial, a chronic alcoholic, came to me at the psychiatric clinic of the military hospital with a note from Major Guérin, giving the details of his nocturnal hallucinations. He saw automobiles arriving, then a German army of 200,000 men, and, in the rear, Russians and French, as well as some Russian vessels. He was then present, he said, at a battle. He fired at the Germans as well as at some aeroplanes. He then saw the domestic animals of his farm.

These hallucinations, which lasted three or four nights, occurred notably at the moment when this territorial was in camp near a railway. He declared, even on coming to himself, that he had really fired at the enemy and at the aeroplane which he saw, but had fired blanks, since he had no cartridges.

However it may be, one sees that the events of war and of battle may supervene among alcoholics, even non-combatants, to give a special form to their oneiric hallucinations. This is only a further example of a very general fact that the events of the moment often intervene

among the insane, to orient and color their delirium and their hallucinations.

### *Mental Confusion and Amnesia.*

Together with hallucinatory oneirism, the predominant syndrome in the psychic disturbances which we are studying is the syndrome of mental confusion. Although constituted by its habitual elements of obtusion, disorientation, amnesia, agitation or torpor, this mental confusion differs in certain points from the type which supervenes, for example, in the course of acute infections. It has a sudden onset like the traumatic cause which produces it; it is not habitually of long duration; and it manifests itself above all by the symptom of amnesia, which is its essential characteristic. The mental confusion produced by battle, therefore, is one of the mental confusions of amnesic type like that of insolation, of polyneuritis and of eclampsia.

Accentuated though the amnesia may be, and exclusive though it may appear in such a case, it does not, however, represent the entire morbid state; it always attaches itself to a mental confusion, perhaps little apparent on account of its slight and transitory manifestations of obtusion and disorientation, but nevertheless real. It even coexists often, as we shall soon see, with hallucinatory dreams, that is to say, with the oneiric element of mental confusion.

The amnesia of cranial traumatisms, like that of insolation or of grave infections, has well-known characteristics. In its typical form it is at the same time lacunar, retrograde, anterograde and actual.

The amnesia which results from battle may present itself under classic aspect. In slight and moderate cases it consists above all of an impression of recollections which extends to a greater or less period from the time of the traumatism, and from the consecutive time. Except for the cases accompanied by loss of consciousness, it is not a complete night, but a more or less sombre twilight and dysamnesia, rather than an amnesia.

That which has appeared to me above all to characterize the amnesia following battle, and to differentiate it in some way from similar amnesias, is that it presents a singular tendency to manifest itself in the complete or total form.

Total amnesia, that is to say, that which extends over the entire life and allows nothing to remain in the subject's mind,—neither his name nor his birthplace nor his age nor his profession, nothing, in a word, of the events through which he has previously lived,—is extremely rare.

I have just observed three very clear cases of this condition among soldiers returning from battle,—two officers and an adjutant profoundly shocked, but not wounded. On their arrival, all three were incapable of furnishing the slightest information about themselves or their families. The adjutant, who had come from Cambrin in a

state of extreme lebetude, which slowly dissipated, was totally ignorant about himself and when he was asked, for instance, if he were married, he looked at his wedding ring and said, "I must be, because here is my ring."

This total amnesia creates in the patients a strange situation from which they suffer more or less acutely. The adjutant cited above reflected, scratched his head when he was questioned and then replied in an irritated tone, "That tires me. I feel that I am going mad."

It is a curious thing that when all the recollections of existence have disappeared there is one which may survive, namely, that of the event which produced the shock. Sometimes even the recollection of this event crystallizes itself in some fashion in the brain, and objectivates itself there to such an extent that from being an agonizing and almost an hallucinatory fixed idea by day, it becomes at night a terrifying hallucination, reproducing itself always during sleep.

Besides the cases of mental confusion and amnesia with more or less marked hallucinatory oneirism, I have observed much more rarely other psychoses among men returning from battle: four cases of anxiety of the melancholic type, four cases of maniacal excitation, and five cases of delirium of vanity among the sick, consisting in auto-attribution of ranks and of imaginary decorations or in circumstantial inventions, notably infallible procedures for the destruction of hostile trenches, with the desire to present the invention to the commander-in-chief or to the minister of war, and with a distrustful fear of being dispossessed of it; but even in these subjects there existed the amnesia and the hallucinatory oneirism, which specifically constitute the fundamental psychic disturbances.

### *Etiology.*

The very minute etiologic investigation which I pursued in every case demonstrated that in psychoses of battle, as elsewhere, the predisposing causes did not lose their effects.

The predisposition observed in patients affected with mental confusion and hallucinatory oneirism is not an hereditary predisposition. We shall see in the second part of this study concerning the ordinary psychoses, that the sons of the insane and alcoholics and, even more, those who had previously had an attack of insanity, have especially fallen or relapsed into illness either at the declaration of war, during the time of mobilization, or in the early days of their service, that is to say, before being under fire. It appears that there was a first selection natural and realized immediately among those who were hereditarily predisposed. On the contrary, there are very few of these predisposed subjects among those returning from the front who have passed under my observation. These were merely disoriented persons whom the first agitations of the early war had not been sufficient

to render insane, or for whom to do so required the shock of battle itself. Such notably were those affected with trench delirium, to whom I shall make future reference.

The individuals in whom the psychoses of battle have supervened, were almost all, and above all, emotionally predisposed, impressionable, nervous, even neuropathic, of whom two had previously had nerve crises of the hysteric type.

This particular predisposition, a true emotional constitution, in my opinion, dominates and illuminates the etiologic mechanism of the psychoses of battle, which are, then, essentially psychoses of emotional origin. This is proved not solely by the habitual existence of the emotional predisposition among the patients, but also by the existence of emotional shock as a principal and constant occasioning factor.

*A priori* one would be tempted to believe that this occasioning cause must be the physical traumatism, the wound and the consequences of every sort which it may entail. This is not so. Of my 50 patients only 22 had been wounded, the 28 others had not received any wound or contusion. On the other hand, not one of them had been without moral and emotional traumatism.

Moreover, the reaction is not delayed and the psychic disturbance appears rapidly, brusquely, either under the form of confusional agitation, driving the patients to rush unconsciously in all directions, sometimes even towards the enemy, crying out and brandishing their rifles, or under the form of inert, passive, catatonic stupor with sometimes more or less profound reactions on the organism.

I observed only a single case of psychosis of truly surgical origin in a man with a wounded hand, with suppuration and fever, who, during this complication, some time after his return from battle, presented an hallucinatory battle delirium with slight symptoms of confusion. The delirium disappeared immediately after incision, and extraction of the bullet. That which provoked the psychosis, therefore, or rather the psychic disturbances of battle, as we have seen and observed them, is essentially an emotional shock of the most violent type in impressionable individuals of a nervous temperament. Of course, physical and moral fatigue, long marches, perpetual alertness, the insomnia of life at the front, prolonged inactivity in the trenches, are all circumstances which, by diminishing the resistance of these subjects, favor the action of emotional shock. It is the same with antecedent diseases, particularly, of course, the intoxications and the infections, latent or chronic, such as ethylism, paludism and tuberculosis. The richest and most durable hallucinatory oneiric delirium that I have observed, was that of two officers affected, one with malaria, the other simultaneously with malaria and tuberculosis.

It is not without interest, from the point of view of age and military status, to remark that of our 50 patients, 29 belong to the reserve,

8 to the active force and 13 to the territorials, and that of this number, there were 35 private soldiers, 10 officers, two adjutants, two sergeants and a corporal. I may add that of the three affected with total amnesia, one was an adjutant and the other two were officers. It appears then, without establishing percentages, that the psychic disturbances of battle affect preferably men of the reserve and show themselves intense, especially in the amnesic form, among officers.

#### *Diagnosis, Prognosis and Treatment.*

The important point of diagnosis concerning the psychoses of battle consists in differentiating them from the ordinary psychoses, that is to say, from the manias. This diagnosis has a capital importance, for it involves at the same time prognosis and treatment.

If it is a question of mania, the attack is serious. It will be long, perhaps inenarrable, and necessitates the commitment of the patient. If, on the contrary, it is a question of a psychosis from mental shock in the form of mental confusion, amnesia, or onerive hallucinatory delirium, the cure is almost certain in a relatively short time and there is no need of commitment, except in extraordinary cases, and if it is a question, for instance, of manic-confusional associations.

From my point of view, it is a serious error, capable of doing great harm at the same time to the patients and to the army, to regard these cases indiscriminately as insane, and to commit them all without observation and previous examination to an insane asylum. These patients, who are but momentarily overturned by an emotional shock, are no more truly insane than those who present stupor, confusion or transitory delirium under the influence of typhoid fever, pneumonia, uremia or a surgical traumatism.

One has no right to inflict the grave measure of commitment on officers or soldiers who return from battle in a temporary state of confusional torpor, or of terrifying hallucinatory onerism, and who, some weeks later, perhaps, will be in a condition to resume their place in the ranks. That is why, in modern wars, particularly in one so severe and so long as the present, there is need of a military psychiatric service. I do not know whether such a service exists elsewhere, but it should do so, for its importance is capital; moreover, it would be easy to organize, even if only in a simple and rudimentary fashion as at Bordeaux.

It would be sufficient, in my opinion, at least for the moment, to establish a psychiatric centre at the military hospital at the seat of each division of the health service. This psychiatric centre, wholly analogous to the delirious wards existing at Bordeaux and Paris, or to the neuro-psychiatric services established in 1900 in the marine hospitals, should be composed primarily like them of several cubicles or isolation chambers for the violent requiring observation, and

an open ward for the calm and inoffensive. These two parts of the service, the cubicles especially, should be, so far as possible, on the ground floor and not far from one another.

This central service should receive not only subjects with psychiatric disturbances from the military hospital itself, but also those of the temporary and auxiliary hospitals of the city and of the neighboring regions. As for the wounded, they may, according to the nature and degree of their psychic disturbance, either remain in surgical wards, or go on to the psychiatric service and there be dressed by the hospital surgeons.

It is indispensable to entrust the psychiatric service to a specialist, supported by at least one assistant and by a competent personnel of attendants whom he shall train. The mobilization, which has placed at the disposition of the directors of the health service a large number of psychiatrists, would greatly facilitate this arrangement.

The function of the physician in these regional centres of psychiatry is at once delicate and manifold. It consists essentially first in receiving all soldiers affected with disturbances predominantly psychic, observing them, and establishing a diagnosis at once rapid and exact; second, in referring without delay to the neighboring insane asylum those affected by mania, by the common psychoses arising on the occasion of war; third, in treating and curing as quickly as possible those capable of rejoining their commands in a few weeks and in forming, on the other hand, a suitable decision in the cases of those more severely affected, particularly those presenting confusional associations.

It may happen that the psychiatric service would receive with the label "psychic disturbance," soldiers attacked by acute infectious diseases. Personally, some time ago, I relieved five in the course of typhoid fever, of whom two came from more or less distant military hospitals in a fairly grave general condition. One ought not to impose a journey on a typhoid patient, especially from one department to another, because he is delirious.

As for the diagnosis between an attack of insanity and a delirium symptomatic of acute infectious disease, the differentiation is relatively easy. It is sufficient to recall that one must think of something other than insanity, and consequently employ every measure of diagnosis every time that a delirium breaks out abruptly; if it presents itself under the form of mental confusion and nocturnal hallucinatory onerism; if it reaches its maximum quickly with stupor or agitation; if it is accompanied by diminished urinary secretion; and finally and above all, if there is fever.

It is obvious that the specialist in charge of the central psychiatric service should, at the same time, fulfill the functions of expert in the war council of the region, these functions being in time of war more important and active than

ever. It is thus that affairs have been organized at Bordeaux since the beginning of hostilities.

## II. NEUROPSYCHIC DISTURBANCES.

The neuropathic disturbances of battle are not easily separated, it appears, from psychic disorders properly so called. Just as the latter, in effect, as we have seen, are accompanied by neuropathic disturbances, notably hysteroid crises, so the neuropathic disturbances are accompanied almost constantly, especially at the outset, either by a certain degree of mental confusion or hallucinatory oneirism or, more often still, by fixed ideas, obsessions and phobias. It was thus in the case of the 38 patients who passed under my observation. On the other hand, these neuropathic disturbances have, in themselves, the closest relations with the psychic condition. They deserve, therefore, the denomination of neuropsychic disturbances under which they are here designated.

Epilepsy is rare. Neurasthenia is more frequent, especially among officers. Already existing or predisposed, it manifests itself with them under the most typical form of exhaustion neurosis with physical and psychical adynamia, apathy, aboulia, and nosophobia. Several of these officers were already fatigued before the war, exhausted by long residence in colonies, and their potential was in advance incapable of enduring the exceptional expenditure of strength required. Some gave way from the outset, manifesting a most vexatious inertia; others, after having given all that they could, sometimes with great brilliancy, collapsed in absolute exhaustion, incapable thenceforth, and ashamed of their incapacity.

As for hysteria, alone or associated with neurasthenia, it is this, or at least that which we are accustomed to classify under this nosologic label, which has largely dominated the scene. The most varied, unusual and peculiar cases may be observed: syndromes of tremor, trepidation, spasm, tic, convulsions, impotence, anesthesia, paralysis, urinary incontinence, blindness, deafness, mutism, somnolence, delirium, sometimes transitory and disappearing at the least suggestion, sometimes tenacious and resistant to the highest degree, accompanied, or not, by classic hysterical attacks recurring daily at the same hour. Almost always these manifestations were met in neuropaths of whom some had already previously had nervous accidents.

For the moment, I only note these facts, and will limit myself to speaking a little more in detail of another syndrome, which, from its frequency, its symptomatology and its relations, seems to me to constitute in some sort the type, or one of the types, of the psychoneuroses of battle. This syndrome is functional paraplegia or pseudoparaplegia.

## *Functional Paraplegia.*

My attention was first drawn to these facts by Inspector-General Delorme, who, on September 13, 1914, asked me to visit and examine at the temporary hospitals Nos. 4 and 78, directed by my colleagues, Drs. Bergonié and LaGrange, a subaltern and a soldier, presenting the effects of explosion, whose nature needed to be determined, this examination presenting great importance from the point of view of prognosis. Subsequently, I observed one after another, six analogous patients, and it is the result of this study that I wish here briefly to summarize.

From the point of view of motility, patients of this sort are all alike. They have at first a more or less complete disability of the legs, preventing them from walking, and even, in certain cases, from standing upright. Nevertheless, the majority have retained their muscular force, as one may determine, by the resistance which they are capable of offering to movements of flexion, or extension imposed on their lower extremities. They can, also, when extended on their bed, raise their feet to a certain height, when the pain which they feel in various points of the body permits it. Only one at his arrival had his legs absolutely inert, and was obliged to take them in his hands to swing them about.

The gait is characteristic. At first, the patients are obliged to lean on someone's shoulders in order to advance, their legs do not bear them, and if they are not supported, they stumble and fall. Then by degrees they succeed in holding themselves upright and, without their feet leaving the ground, dragging them one after another on the floor, supported by the sides of their bed and surrounding furniture, or on two stout canes, which they do not dare to give up, they walk very quickly with efforts of the trunk and arms to aid them.

Cutaneous sensibility is more or less diminished, especially in the lower extremities, where it is at times completely abolished.

The reflexes are variable. In a general way the tendon reflexes are preserved, sometimes even exaggerated, while the cutaneous reflexes, on the contrary, are very slight.

I have not observed in my patients either trophic disturbances or paralysis of the sphincters. In two, there occurred temporary anuria and obstinate constipation. There are almost always headache and variable pains, notably in the lumbar region and in the legs, increasing under the influence of attempts to walk and augmenting, in turn, when they are more acute, the difficulties of locomotion.

In seven out of eight cases, I was able to have an electro-diagnosis by Professor Sigalis and Dr. Nancé Penard. In all, the examination showed complete absence of reaction of degeneration; it showed qualitative modification of electric irritability and the existence of simple, qualitative variations, most often with diminution of faradic irritability for the muscles of

the antero-external region, either of one leg or of both, more rarely for the muscles of the thigh.

In fact, one does not observe in these cases any sign of organic lesion, and the diagnosis of functional paraplegia appears self-evident. This diagnosis, I insist, is applied solely to the category of cases which I have observed. Without doubt, there exist also, between the functional paraplegias and the organic paraplegias, mixed cases; that is to say, cases of association in diverse degrees of nerve alterations and of neuropathologic troubles, as is so frequent in neurology.

The evolution of the malady is ordinarily very slow. Either the disability continues to amend, but in a rather imperceptible manner, or else it remains almost stationary, with slight increases and diminutions, with moments of improvement followed by abrupt relapses on trifling cause, such as pain in the legs, in the back, in the head, or a simple obstinacy, with tendency in each one to adopt a mode of gait determined, and more or less invariable.

Of my eight patients, a single one rejoined his command, still not cured. Of the seven others, two are making progress, but still rise with difficulty from a chair and can hardly walk without support; four are better one day and worse the next; and one is still at the same point, and drags his feet on the ground as at the first day.

In short, incomplete cure in one case, very slight amelioration or almost stationary condition in all the others. This at the end of two months is the situation in my patients, in spite of the active internal and external treatment which has been employed with strychnine, tonics, massage, electrotherapy and hydrotherapy.

The etiology deserves here particular attention. One would be tempted at first to attribute the principal rôle to a special action exercised in the explosive zone of bombs, and an action produced either by the wind of the projectile or by the sudden displacement and rarefaction of the surrounding air, or by the liberation of toxic gases, or by the raising or throwing down of the body, sometimes even with loss of consciousness following and capable of determining true nervous alteration. I believe, in accordance with the facts which I have observed, that this is not the case; for besides the actual symptoms of the disease which make an organic lesion unlikely, there are other reasons of an etiologic nature, which in themselves would suffice to permit this diagnosis to be abandoned.

The principal one of these reasons, evidently perceptory, is that the patients affected with this form of paraplegia have not always been found in the explosive zone of a bomb. Two of our men, out of eight, had been merely and slightly wounded in the foot with a bullet. Moreover, in one of these cases, the paraplegia did not supervene until three weeks after his return from the front to the hospital, when his wound had almost healed. Nevertheless, the clinical

manifestations were identical in all the cases. There was the same characteristic disability of the legs and shuffling gait. We must, therefore, seek elsewhere, if not the sole cause, at least the principal cause for this singular syndrome.

This cause, in my opinion, admits of no doubt: it is, again, emotional shock. Not only has emotional shock never been absent in our patients, but one learns that in all it has played the essential rôle, whether they have been overcome by the nearby explosion of shell, or wounded by a bullet, whether overcome immediately, or after an interval.

A final proof establishes the certainty that these patients are the victims of their emotionality: it is that this same emotionality persists, and dominates the picture during the entire course of their disease. That is why, when they wish to walk, they hesitate, tremble and are apprehensive, as in the *astasia-abasia phobia*. It is that which, by reason of their suggestibility, holds them under the menace of a fixed idea of disability, of paralysis, of incurability, as in *sinistrosis*, of which cases of this sort are, at bottom, only a variety. It is this, finally, which in almost all determines, at the same time as the nervous disturbances, the more or less marked psychic disturbances of confusion, amnesia and hallucinatory *oneirism*. From this, one can explain perfectly the evolution of this functional paraplegia, entirely subordinated to the emotional mentality of the subjects, ameliorating or growing worse with it, capable even of prolonging and fixing itself indefinitely, when it is associated with some auto-suggestion, some underlying, fixed idea.

I cannot here pass over in silence the very interesting experiences of Dr. Moulinier, on the one hand, upon the prolonged apnea of vagotomized animals exposed to the action of a sudden detonation; on the other hand, upon the psychic and nervous disturbances presented by dogs subjected to the influence of a violent explosion. It is a peculiar fact that certain dogs present psychic and nervous disturbances, recalling those which we have just described, particularly *hebétude*, *pantophobia* and *sluggishness of gait in the hind legs not extending as far as paraplegia*. It is well to add that in these dogs, which died at the end of three or four days, autopsy revealed no microscopic lesion of the nerve centres, nor any organic disorder. Hence, the conclusion of the author, identical with ours, that it is highly probable that the disturbances observed are purely functional and develop only in predisposed subjects.

In conclusion, I believe that functional paraplegia following battle must be regarded as the effect of a violent emotional shock. It is to be recalled, moreover, that functional paraplegia of emotional origin is already known to pathology and that cases were cited, especially by Déjerine, Babinski and Sollier, in the course of the memorable discussion on the rôle of emotion in the genesis of neuropathic and psychopathic

accidents, which took place in December, 1909, at the joint session of the Societies of Neurology and Psychiatry, at Paris.

I may add that there is something comparable in confusional psychosis and particularly in the amnesia produced in the same conditions. These are, in my opinion, two morbid manifestations of the same emotional shock under the form of a phenomenon of arrest, of inhibition, with this difference: that one affects the psychic functions and the other the medullary functions, the two, moreover, as we have just said, being capable of co-existence.

What is difficult to explain is the reason why, when the emotional shock of battle acts on the system, it translates itself preferably into a functional paraplegia. One commonly says of an individual overwhelmed by a violent and sudden moral traumatism that the emotion has taken him off his feet. This familiar phrase is very exactly applicable here, but does not explain why the nervous shock of battle customarily and, so to speak, systematically, affects only the legs and not the arms.

Doubtless it is simply because intense emotions react particularly on the lower extremities in man, as in animals, by reason of their notably lower resistance to various inhibitory agents, but I am far from declaring, the more so since the number of cases which I have observed is small, that this is the rule, and that functional inhibition never affects the upper extremities.

There remain two points to examine. The first is that of the frequency of functional paraplegia as a neuropsychic accident of battle. I should be disposed to believe that this accident is relatively frequent, for it is by chance and without search that I have been able to observe eight cases. Moreover, three similar cases, wholly identical, have been referred to me by Dr. Moulinier, Dr. Drivet and Dr. Bernadon, bringing the number of observations of this sort to eleven.

I should not be surprised if this accident which, if I may judge by my cases, seems to be found chiefly in soldiers of the active force and in young reservists, were an accident of the beginning of the war, becoming less and less frequent in proportion to the marvelous adaptation of soldiers to the terrible effects and circumstances of war. The eleven cases of functional paraplegia which I have cited all date from the month of August or the beginning of September, 1914. Personally, I know of no more recent cases.

The second point to be examined is that relative to the disposal to be made of cases of this sort from the military point of view. This point, as was indicated at the outset by Inspector General Delorme, is very important, so important that, before inviting or advising a decision relative to soldiers affected with functional paraplegia, I have considered it a duty to follow them closely and for a long time. Even today,

at the end of three months, I am not decided and still hesitate.

Considering only the proved fact of so marked and so long a disability of the leg, which threatens to become permanent, a single solution seems to be imposed; namely, the workhouse. Regarding it more closely, things are less simple than they appear. Functional paraplegia due to emotional shock of combat is, I repeat, a true *sinistrosis*. Like *sinistroses* which frequently disappear after the decision of the court, it has, therefore, a great chance of disappearing also. This is vexatious, the more so, that among soldiers everything is known, repeated, and imitated and this, therefore, cannot fail to multiply cases of this sort, at least to influence their evolution and prognosis. What, then, is to be done with these cases? It would be very imprudent to endeavor, in spite of their non-cure, to send them back to the front, not merely because their condition would infallibly become aggravated there, but also because they are, at bottom, nervously predisposed and even if they supersensitize, if they add voluntarily or not to their morbid manifestations, are none the less sick, delicate, fragile, that is to say, for the greater part, soldiers of inferior quality.

On the other hand, one cannot think of keeping indefinitely in a military hospital where, in time of war, movement ought to be as rapid as possible, an unfortunate cripple destined in the end to weary the most enduring patience. Moreover, placing one of these nervous wrecks in a workhouse is liable to provoke imitators. How much more susceptible of contagion in an institution of *psycho-neuropaths*, the spectacle of this infirmity of so pitiable an aspect! I have proof that my patients make less progress the more one sympathizes with their disability, and proofs that, unconsciously or not, they react on one another; and I might cite those of my pseudo-paraplegics who have a nerve crisis for the first time after having seen a hysterical attack.

The best solution of this difficult medico-military problem would be that of parole under observation, like that adopted by the law in industrial accidents. But in time of war there is no leisure to wait, and temporary discharge, like renewable convalescence discharge, is not of a nature to solve the difficulty. Perhaps it would be best, after all, for the purpose of suppressing all possibility of *sinistrose* auto-suggestion created by the prospect of complete liberation, to keep these subjects in the army, giving them, if possible, an employment compatible with their morbid condition. It is obvious, moreover, that here, as always in medicine, it can be a question only of kind, and that each case, after examination, must be disposed of according to indications.

In conclusion, it should be said that subjects affected with neuropsychic disturbances should be separated from other patients and placed in

a special neurologic or neuro-psychiatric service, in accordance with local organizations, reducing to a minimum the chances of intermental action, that is to say, of reciprocal contagion.

## DRUG ADDICTION AND MODERN METHODS FOR ITS CONTROL.

BY SOLOMON H. RUBIN, M.D.,

*Physician to Out-Patient Department, Norfolk State Hospital; Instructor in Histology and Biology in Tufts College Medical School.*

SINCE the federal and state governments have officially recognized the gravity of the narcotic-drug evil, and have enacted laws prohibiting and penalizing the indiscriminate sale and the habitual use of such drugs, the question of cause and the control of drug addiction came to the foreground.

The Harrison and state anti-narcotic laws have been responsible for the active and vigorous campaign against the habit-forming drug evil, the crusade being headed and conducted by local police and federal authorities. The conspicuous activity of these officials has overshadowed the real nature of the evil by lending to it a criminal aspect, thus branding narcomania with the stigma of crime and prescribing a penalty for the offence.

For years the drug menace has been permitted to flourish more or less unchecked until it has become so deep-rooted as to be ineradicable. Suddenly our legislators were awakened from their lethargy by the alarming spread of the addiction in this country, with the result that law upon law, intended to uproot the evil, has been inscribed on the statute books; all of which though well intentioned, have failed as yet to strike at the core of the trouble.

Although our laws forbid habitual indulgence in and the indiscriminate sale of habit-forming drugs, none provides a remedy other than the penal institution. As a result drug addiction has failed to attract the merited attention of the medical profession, which regarded it outside of its field of investigation, and unconsciously coincided with the penologist that drug-addiction is purely a social evil and should be dealt with by punitive measures.

Those who come in professional contact with the narcomaniacs are convinced that drug-addiction is a definite disease having a well defined symptomatology and an indefinite pathology. Indeed, the symptoms of abstinence in almost all cases appear with regularity, in classical order, and so constant as to constitute a definite disease condition which may be easily recognized by the train of symptoms it represents.

Granting, therefore, that we are dealing with

a definite disease, the question of susceptibility, cause, and treatment presents itself for consideration.

The question why men and women indulge in narcotic drugs is as yet unanswered. The combined researches of the psychologist, the sociologist, the alienist, and the criminologist have not been productive of a satisfactory explanation. It is said that men drink alcohol and indulge in narcotic drugs because they have an instinctive desire for some form of stimulation, and for the same reason indulge in tea, coffee, and tobacco. Not always are habit-forming drugs used to stimulate sluggish mental faculties or to slow down an overactive mind. In either case, when so used, the element of time and protracted use soon reduces, and ultimately destroys, the efficacy of the drug, both as a stimulant and as a depressant, and the individual takes it thereafter to maintain a normal mental and physical tone. Finding himself in the throes of a permanent habit, the addict uses narcotic-drugs as a connecting link to join the break, which his habitual indulgence produced, in the chain of normal mental and physical functions.

The continued gratification of a craving for artificial stimulation establishes in the habitué a vicious circle of disease, poverty, crime, and punishment, each one following the other in sequential order, and reacting upon each other until a break in the continuity of the circle is brought about through abstinence. Abstinence brings on a series of mental and physical disorders which require the restraining influence of a normal will-power, the lack of which compels the user to resort to drugs in order to obtain relief. Thus the habit becomes deep-rooted, the vicious circle continues to operate, the addict develops into a pathetic figure, and is finally reduced to a state of mental and physical deterioration.

The opportunity to study the addict, to discuss with him every angle of his addiction, to see him leave the hospital apparently cured, and to see him return repeatedly for readmission to the institution as a relapsed case, in extenuation offering a variety of plausible excuses, is afforded in the out-patient department of the Norfolk State Hospital where alcohol and drug inebriates apply for treatment. Close observation of these cases before and after treatment suggests that addicts become such because of an inherent or acquired mental weakness, and that in most cases it antedated their habitual indulgence in habit-forming drugs. In other words, it is the neuropath and psychopath who seeks in narcotic-drugs the missing link in his chain of normal functions, the restoration of which makes him feel "just right." With this contention in mind the main reason for our inability permanently to cure a fully developed drug addict becomes obvious. Even the widely advertised "quick cures" have failed to reduce the number of drug users and to make even a lasting impression upon the patient.

Those who have to treat addicts appreciate the futility of relying wholly on the innumerable pharmaceutical remedies so widely and variedly employed in combating the narcotic-drug habit. Successful treatment does not end with the discharge of the patient from the hospital. The real struggle begins at that stage, and becomes more intense and trying with each succeeding day.

Failure permanently to cure drug addiction is due to three powerful influences which assail the patient after treatment and discharge from the hospital. One, the distressing symptoms of abstinence, which gradually reappear and react upon the patient's power of self-control, destroying the stability of purpose that has been inculcated in the patient during his stay in the hospital; two, his return to the same unchanged social environment, which was probably the original cause of the victim's addiction; three, the patient's inferior mental stamina, which he may have acquired or inherited, but which renders him a prey for any form of stimulant. At any rate, the treated patient who has been pronounced "cured" almost invariably lacks the disposition or will to remain abstinent, and the slightest pretext or the most indirect suggestion is sufficient grounds for relapsing.

Hence it may be assumed that something more than purging, nauseating, depressing, motor-exciting drugs must be resorted to if success in the cure of narcotic-drug addiction is to be attained. To attain the desired end entirely different forces should be enlisted in the treatment,—forces employed by the psychologist, the alienist, the neurologist, and the internist.

Obviously, pharmaceutical remedies have but a single place in the treatment of drug-addicts. Using such remedies to alleviate or ameliorate the distressing symptoms of abstinence, and by combining with them the measures employed by the different specialists, one would offer to the patient a more reasonable and hopeful chance for cure than is afforded him by the hasty empirical methods used in institutions that advertise their "quick cures" in a rather alluring manner.

Successfully to cure drug addiction the addict should be treated in a hospital or institution specially constructed to receive such cases. To prevent escapes at the critical period of their treatment, and to provide for temporary close confinement which proper treatment necessitates, suitable and comfortable quarters with good ventilation and plenty of sunlight should be provided. Drug addicts are notoriously unreliable and should be closely watched; their quarters should be frequently searched for smuggled drugs. The seeming sincerity they display and their manifest inordinate desire for relief from their addiction would deeply impress the inexperienced, yet few addicts have been able to maintain for any length of time the same degree of interest in themselves which they so zealously manifested on previous occasion.

If only for these reasons the addict should be treated in an institution and not at the patient's home, and for no less a period than a year. Such prolonged and enforced residence in an institution may seem arbitrary and in effect unnecessary for the rare, earnest, and sincere addict, but experience with a large number of users dictates the need of employing such peremptory measures, successful treatment being attained only by adopting them. One can see the hopelessness of attempting to treat narcotic drug addiction in private practice, especially while the patient is free to enjoy any quantity of drug he may desire regardless of his physician's instructions. The honest physician should not undertake to treat such cases under such conditions. Whether the law should be amended prohibiting the physician in general practice from treating narcomaniacs at home and limiting him to the prescribing of narcotic drugs only in extreme emergency cases is suggested by the inevitable failure of home treatment and the opportunity it has opened up for the unscrupulous physician, to carry on a nefarious trade in narcotic-drugs. It seems that if that part of the Harrison Law were repealed and the law so amended as to limit the practicing physician to the prescribing or dispensing of narcotic-drugs only to meet emergency needs in his legitimate practice of medicine, the sordid and harmful practices of the unscrupulous physician could be obviated. Such a change in the law would indeed affect the honest practitioner, but the limitation would entail no hardship upon him if he would appreciate the futility of giving home treatment to drug addicts by the reduction method without the exercise of some form of restraint, such, for example, as could be obtained in an institution.

The aged user, the paralytic, and others too far gone for treatment, must have their daily supply. Who shall prescribe for them? The question, to be properly answered, must involve the proposition limiting the manufacture and sale of narcotic-drugs to government agencies, and the right to dispense narcotic-drugs to local boards of health. By so centralizing the source of supply in local boards of health and by compelling the druggist, the physician, the dentist, and the consumer to obtain their supply from this source, the irredeemable user could be taken care of and the unscrupulous physician and druggist would be eliminated, permitting the crusade against the evil to progress without hindrance from that source. At the same time, the redeemable addict could be induced to enter an institution for treatment, even for a protracted period, if his source of supply is completely cut off.

These suggestions apply only to the social users, of which there are approximately seventy percent. The criminal and delinquent type, of which there are approximately twenty percent, are subjects for the penologist and criminologist. This class of users is the most hopeless and

most dangerous element to deal with. They are intractable, cunning, designing, and wholly devoid of moral responsibility. It is their ambition to enlist new victims in the army of drug users, making it their business to keep them constantly supplied. In this class may be found the drug peddler, the white-slaver, the pick-pocket, the panhandler, and the all-round crook. Therefore, the successful eradication of the evil and the uprooting of the traffic would necessarily entail a disposition of this class of narcotic-drug users. With the elimination of this class the task of caring for the social user and for those who have contracted the habit through illness would be less difficult. The latter class constitute approximately ten percent of users, and indulge in drugs only to maintain a normal mental and physical tone.

The activity of the authorities in rounding up drug users and meting out to them the penalty imposed by law may be commended when it affects only the criminal class of users. But when the crusade is made general, affecting the redeemable social user the responsibility rests with the medical profession for having failed to recognize the condition as a definite disease, and to urge the employment of medico-social measures instead of penal measures in the rehabilitation of the unfortunate victims. The condition may still be remedied if the federal government and our legislatures would provide ample and suitable facilities for the care of the addict.

The penal institution has never cured the drug and alcohol inebriate. Unfortunately many addicts have been initiated to the use of habit-forming drugs in such institutions, taking it principally for the purpose of creating a euphoria to take the place of the depression which jail walls produce. On his discharge from the penal institution, the addict finds himself without moral fibre or mental strength, the need of which is obvious, if he is to be restored to his normal self.

Unfortunately the Harrison law provides that the addict should be deprived of his supply, but does not provide for his care. In other words, the law as it stands today drives the addict to employ the very means of procurement which it aims to contravene. Much of interest could be written on the methods employed by the addict to procure drugs. Where fair means fail, foul measures are unhesitatingly adopted. He who was meek and mild prior to addiction, is transformed under the stress and strain of enforced abstinence into the desperate habitué cunningly overcoming every obstacle which may be in the way of his obtaining sufficient funds with which to purchase his supply of drugs. In spite of our anti-narcotic laws, addicts apparently experience little difficulty in securing a plentiful supply. The price may be exorbitant, often productive, the product poor of quality and usually adulterated, yet these are not barriers to

procurement when the symptoms of abstinence manifest themselves in the patient. Many of the breaks and entries of police record have been committed in all probability by the cocaine habitué in his effort to obtain funds with which to procure drugs.

The police authorities of Massachusetts, appreciating the importance of segregating the different classes of drug users, have shown a disposition to give the habitué a chance, and the Norfolk State Hospital is being frequently called upon by the officials, to make analyses of doubtful cases and to advise what disposition should be made of them. In other states the addict's chances are not so good. The social user, the criminal, and he who contracted the habit through illness are thrown together and handled as a single class of offenders. As a result the social user comes in intimate contact with the vicious type, contracting, so to speak, his criminal tendencies and methods. This state of affairs should be done away with.

Contrary to the prevailing opinion of the medical profession and the laity, the majority of drug-users have themselves to blame for their addiction. These facts have been gleaned from addicts, approximately seventy percent of whom admitted on close questioning that their enslavement in drugs is due to their own manner of loose living and indiscriminate social relations with users. Thus stands the medical profession as a whole exonerated from the oft-repeated charge that its members are responsible for the widespread addiction among men and women. In this respect it may be said that as a general rule an addict's confession or admission is to be regarded with suspicion, and should be relied upon only when corroborated by others in whom confidence can be reposed. But when an addict places the responsibility of his folly upon himself, accepting whatever disposition his examiner will make of him, his statement may be regarded as true.

Unfortunately the medical profession does harbor unscrupulous physicians who have undoubtedly done much to further the spread of the evil. These men are responsible for the general accusation against the profession in this as in other things. Jail sentence is the only remedy for them.

Even the honest but untaught and inexperienced physician has undoubtedly unconsciously induced the habit in patients ill with a painful malady by prolonged administration of habit-forming drugs. He should be educated.

In the interest of the seventy percent of social users of narcotic-drugs, which constitute the desirable class for institutional treatment, our legislatures should be urged to provide suitable and adequate facilities for their proper care along modern and rational lines, that they may be restored again to useful citizenship and to society. These facilities should be provided, as Dr. F. H. Carlisle suggests, on an island far away from outside interference.

## Clinical Department.

### ACUTE PRIMARY "IDIOPATHIC" PHLEGMONOUS GASTRITIS. REPORT OF A CASE WITH BACTERIOLOGICAL FINDINGS.\*

BY EMANUEL B. FINK, S.B., CHICAGO.

By this term is generally understood a purulent inflammation of the stomach wall, which most often localizes in the submucosa, and there leads to more or less extensive pus formation but which may also affect the mucosa, muscularis, submucosa and serosa.

On the basis of etiology, phlegmonous gastritis is divided into two classes.

1. The primary or idiopathic forms, in which a direct cause is not demonstrable.

2. The secondary forms. The latter are again divided into three sub-groups.

a. Direct extension phlegmons, *i.e.*, those following oesophagitis.

b. Local secondary phlegmons which follow ulcer, carcinoma, or an operation.

c. Metastatic secondary phlegmons, in which infection of the stomach follows infection of some other part of the body.

On the basis of pathologic anatomy two forms are distinguished: the diffuse phlegmonous gastritis, in which the pus infiltration spreads diffusely over a considerable area, and the circumscribed form or gastric abscess. Strictly speaking, only the former should be included among the cases of phlegmonous gastritis.

The primary or idiopathic phlegmonous gastritis (Hosch<sup>1</sup>) is the most frequently encountered, and our case also belongs to this class. It is not our purpose to give an extensive review of the literature, as several excellent reviews are on record, among the more recent of which is that of Bossart<sup>2</sup> in 1912, which consists of a comparative study of all cases which the author was able to find with a complete bibliography. Among the earlier papers may be mentioned those of Schnarrwyler,<sup>3</sup> Robertson,<sup>4</sup> Adams,<sup>5</sup> Koenic,<sup>6</sup> Jensen,<sup>7</sup> in 1911, recorded the detailed histories of ten Danish cases, and found 121 on record elsewhere. In the literature before 1911, Bossart was able to collect 110 cases of circumscribed and diffuse phlegmonous inflammations of the stomach wall. Emge,<sup>8</sup> in 1914, thought that only one-half the cases reported, or about 50, were true primary, or idiopathic phlegmonous gastritis. It is difficult to make a correct estimate without running down each case recorded, but most authors are agreed that the idiopathic variety is the one most commonly observed.

The history of this case was kindly furnished me by Dr. Paul Oliver of the Surgical Staff, of the Cook County Hospital.

The patient was a laborer, 58 years old, of Swedish nationality. He entered the hospital Dec. 24, 1915, because of a large inguinal hernia on the right side, which had slowly grown in size during a period of eight years. It had never been painful or irreducible, and he wished to have it attended to because of some discomfort and interference with heavy work. He also stated that a swelling of the left forearm had developed and persisted, following a fall upon the hand one week previously. He had noted some edema of the ankles during the past year. About a year ago the patient had been in the hospital on account of broken compensation. He further stated that at one time he had been a heavy drinker, but had not taken liquor in recent years. He had had some nocturnal frequency of urination. Otherwise the history was negative.

Upon physical examination, the man appeared to be obese, with ruddy complexion and a moderate acne rosacea. The mouth was in bad condition; teeth decayed, pyorrhea alveolaris, tongue swollen and covered with a brown coat. The tonsils showed some enlargement. Except for a few mucous râles the lungs were negative. The heart dulness was increased. There was a systolic murmur transmitted to the axilla and an accentuated second pulmonic. The abdomen was negative, except for the liver, which was palpable two fingers' breadth below the costal margin. In the inguinal region there was a large hernia which passed down the inguinal canal and was easily reducible. A smaller hernia was present on the left side. There was a soft edema of both ankles. There was swelling and discoloration of the left forearm and hand which the Roentgen plate showed to be due to an incomplete fracture of the radius. The urine showed a specific gravity of 1.012, a trace of albumin and granular and hyaline casts. From these findings a clinical diagnosis of right complete indirect, inguinal hernia, left incomplete hernia, decompensated heart lesion, chronic nephritis and recent left Colles fracture was made.

After a period of appropriate medical treatment the patient improved, so that on Jan. 4, 1916, a repair of the right hernia under local anesthesia was made by Dr. Ryan. The post-operative course was normal in every way until the night of January 15, about ten days after the operation, when he complained of a chill and his temperature rose to 101.6 with a pulse of 96. He then complained of pains in the abdomen, especially in the epigastrium. During the next three days the temperature ranged between 99.8 and 102, with the pulse becoming more rapid and the pains more severe. During the night of January 17, the patient moaned all night because of the severe pain. He did not vomit at any time.

Dr. Oliver first saw the case on the 18th of January and found the patient with flushed face and apparently in distress, with respirations rapid and shallow, temperature 101.2, pulse 130, irregular and weak. The abdomen was rigid and somewhat tender in the epigastrium. The patient pointed to the epigastrium as the source of the trouble. There seemed to be slight shifting dulness in the flanks. A probable diagnosis of general peritonitis was made, the source of which was difficult to determine, a perforated gastric ulcer being thought most likely. Immediate operation was decided upon, and under ether anesthesia, the abdomen was opened through a right rectus incision. As soon as the peritoneal cavity was entered a few ounces of a dark sero-pus escaped. Exploration of the lower

\* From the Department of Pathology, University of Chicago.

abdomen was negative, except for a hernia on the left which contained an appendix epiploicum. There was only slight injection of the peritoneum in this region, but the serosa of the bowel of the upper abdomen showed marked injection and some fibrinous exudate. The omentum was found firmly wrapped about the stomach, just as it is often found about an acute appendix. Upon its separation, a large amount of pus escaped and revealed the stomach a uniform angry red, having the appearance of a very acutely inflamed appendix. The wall was stiff, thick, indurated and edematous and the process seemed to involve the entire organ, stopping abruptly at the pyloric sphincter. The duodenum beyond could be felt thin walled, and apparently normal. The pylorus felt like a solid mass. Careful search was made for a perforation without success. Nothing further was attempted, the patient being put to bed with tubular drainage in the suprapubic stab wound and upper abdomen. The patient did not react after operation and died in about eight hours.

The post-mortem examination was made on the afternoon of the same day, January 19, 1916, by Dr. H. Gideon Wells, to whom I am indebted for the abstract from his autopsy records and for permission to work up the case.

The following is an abstract of the autopsy notes on this case:

*External Appearance.* The body is that of an obese man. There is a slight yellow coloration of the skin. The superficial lymph glands are not palpable, except those of the right groin. There is some edema of the legs. The scrotum is reddened, and in the right side is an indurated mass about 5 cm. in diameter, continuous with the testicle. There is a little hernial bulging on the left side. In the anterior abdominal wall are two openings, one above the pubic crest and extending to almost the costal margin above the outer border of the right rectus. There is another drain in the lower portion of the latter.

On palpation, there is an indurated mass along the course of the right inguinal canal. Above the umbilicus is a circular nodule in the subcutaneous fat, 7 mm. in diameter. There is a recently healed surgical wound parallel to the right Poupart's ligament.

*Abdominal Cavity.* There is a considerable amount of subcutaneous fat, about 5 cm. in thickness. The upper drainage tube passes between the liver and stomach, deeply into and over the lesser curvature to reach the retroperitoneal tissue. The peritoneal surface is very much reddened. The lower tubular drain runs into the cul-de-sac of Douglas in which there is a small amount (30-50 c.c.) of purulent fluid. A cigarette drain runs between the intestines. The peritoneal coat is injected, but for the most part is shiny. In the intestines of the peritoneum are pockets of purulent fluid but no large accumulations of fluid, and no fibrin. The left inguinal ring is open and admits two finger tips up to the external ring, after which only one finger tip is admitted. The right inguinal ring is closed. The mass consists here of fibrofatty tissues in which are small hemorrhages. There is no evidence of infection or suppuration here. The peritoneal surface in this region is puckered, but no infection is present.

The mesenteric lymph glands are not enlarged, but there are small pigmented spots and a small calcified fibrous strand in the peritoneum. The ap-

pendix is free but atrophied. Such pigmented areas are also found 20 cm. above the ileocecal valve. There is one particular area, one mm. in diameter, in which the peritoneum is necrotic and a necrotic tissue protrudes, but there is no perforation. There are no perforations in the small intestines. In the lesser peritoneal cavity there is a little purulent fluid but no perforations. The lesser peritoneum is free from adhesions. Some fibrous adhesions are present about the spleen; also a few about the sigmoid. The diaphragm is at the fourth interspace on the right side, and at the upper border of the sixth rib on the left.

*Gastro-intestinal Tract.* In the intestines there is a small pigmented area in the ileum, but no ulcers. The stomach shows a markedly hyperemic but smooth serosa, and on palpation shows diffuse thickening of the wall but no great induration. The thickening is most marked above the pylorus. On the lesser curvature is a point of irregular perforation limited to the serosa where the drainage tube was located. There are no adhesions about this perforation. Upon opening the stomach, the mucosa is seen to be diffusely hyperemic with hemorrhages beneath the mucosa. Folds of mucosa are missing. There is a purulent infiltration of all parts of the wall, and when cut, creamy yellow pus oozes out. The infiltration extends from the cardiac orifice to the pyloric valve, where it stops abruptly. The mucous membrane is everywhere intact. The purulent material forms a layer apparently in the submucosa, one to four mm. in thickness, the pus oozing out slowly from the cut surface everywhere. The stomach is heavy and boggy, weighing 440 grams, emptied. No ulceration or tumor masses are visible. The mucous membrane is swollen and edematous. There is some hemorrhage in the mesogastrium, but no adhesion about the stomach.

Other autopsy findings are indicated by the following:

*Anatomical Diagnosis.* Acute diffuse phlegmonous gastritis. Acute suppurative peritonitis. Two recent laparotomy wounds with drainage. Recent healed herniotomy incision. Remains of hernial sac in right inguinal canal with hematoma. Chronic interstitial nephritis (red granular kidney). Thrombotic occlusion of anterior coronary artery with anemic necrosis in left ventricle. Hypostatic congestion and edema with broncho-pneumonia in right lower lobe. Slight atrophic cirrhosis and passive congestion of the liver. Parenchymatous degeneration of the liver and spleen. Fibrous peritonitis. Senile arteriosclerosis with atheroma. Edema of lower extremities. Obliteration of left tunica vaginalis testis. Necrotic masses in serosa of ileum. Lipomatous nodule in anterior abdominal wall. Diffuse fibrous myocarditis.

*Histological Examination.* The surface of the mucosa shows only post-mortem changes. Just beneath the surface there are small areas of hemorrhage. In the deeper portions of the mucosa, bordering on the muscularis, there is a diffuse infiltration of polymorphonuclear leucocytes. Scattered throughout this area are small masses of bacteria. The muscle bundles in the muscularis mucosa are widely separated and the spaces between are filled with polymorphonuclear leucocytes. In the upper layer of the submucosa there are two large circumscribed areas consisting of polymorphonuclear leucocytes and small masses of necrotic connective tissue and elastic fibers. Between these two areas of

suppuration the submucosa shows only a diffuse infiltration and some fibrin. The deeper layers present the same picture. The serosa is normal. Apparently the pus infiltration of the submucosa occurred in two bands separated by a wall which had not yet been replaced by pus, and only the upper layers of the submucosa were involved in the process. The diagnosis was acute interstitial phlegmonous gastritis, with marked suppuration of the submucosa and muscular coat, but no ulceration of the mucosa.

**Bacteriological Findings.** Microscopical examination of pus smears taken from the wall of the stomach and stained with methylene blue showed pus cells filled with chains of diplococci, four to six pairs to the chain. Scattered through the field were single diplococci. Careful search of several smears failed to reveal any other organism. Other smears stained with Giemsa's stain showed that the pus consisted almost entirely of polymorphonuclear neutrophils containing this same short-chain streptococcus, for the most part intracellularly.

Cultures were made on January 19, 1916, the day of the autopsy. After searing the surface of the stomach wall, pus was aspirated with a sterile Pasteur pipette. The contents were then smeared over the surfaces of agar and blood serum tubes, and also inoculated into broth. In addition, some of the material was plated on blood agar. Both aerobic and anaerobic cultures were made; the anaerobic cultures being placed in a Noy jar, and the pyrogallie acid method used to obtain anaerobic conditions.

After twenty-four hours the broth showed a uniform turbidity. On shaking, a faint cloud could be seen whirling through the medium. On slant agar there were discrete, dewdrop, moist colonies, each about 0.5 mm. in diameter. Growth was very poor. On Loeffler's blood serum, there was a pale, yellowish-brown slimy growth covering the surface. The surface of the medium had not been digested. Smears from these cultures showed the same organism that had been observed in the pus smears, and here, too, it occurred in short chains and diplococci. It retained the stain by Gram's method of staining. Subcultures made on all the ordinary laboratory media gave all the cultural characteristics of the streptococcus group. On blood agar (human blood), there appeared small pin-point colonies, with a clear zone of hemolysis about one mm. wide around them. The cultural characteristics were the same, both aerobically and anaerobically.

The fermentative reactions of this organism were studied, both aerobically and anaerobically. For this purpose three loopfuls of a twenty-four hour old broth culture were inoculated into tubes containing ten c.c. of sugar-free broth, and one per cent. of the sugar or carbohydrate to be tested. In addition, each tube contained enough of a one per cent. litmus solution to give it a distinct blue color, and a small inverted fermentation vial to show gas formation. The substances tested were dextrose, lactose, saccharose, raffinose, dulcitol, arabinose, salicin, sorbitol and xylose.

The aerobic culture fermented dextrose, lactose and salicin with enough acid formation to impart a distinct red color to the litmus, but without gas formation. The cultures containing dulcitol and sorbitol were very faintly acid, and showed no gas. Saccharose, raffinose, arabinose and xylose were unaffected.

Anaerobically the organism fermented all the sub-

stances tested with the formation of acid. In the cases of dextrose, lactose, saccharose, dulcitol, sorbitol and xylose enough acid was formed to completely discharge the color of the litmus. Gas was formed in all the tubes, varying in amount from a single bubble in those containing saccharose and salicin, to a tube-full in those containing dextrose, raffinose, dulcitol and sorbitol.

Experiments were also carried out in an attempt to reproduce this condition in animals. A rabbit was injected intravenously with a twenty-four hour broth culture and died the next day showing all the findings of an acute toxemia except an enlarged spleen. The organism was recovered in pure culture from the heart's blood. Several animals were thus treated with the same result.

Two guinea-pigs were injected intra-cardially with one c.c. each of a twenty-four hour culture and died the next day of acute toxemia. In none of the rabbits or guinea-pigs did the stomach show any lesions whatever.

An aseptic operation was performed upon a dog in which a twenty-four hour growth on agar suspended in sterile salt solution, was injected into the wall of the stomach, through a laparotomy wound. The animal recovered from the operation and the wound healed, but no symptoms of illness developed after two weeks. The same dog was then given an intravenous injection of another twenty-four hour growth, without showing any ill effects after forty-eight hours. A subsequent intra-cardiac injection of the same organism caused death within twenty-four hours. A streptococcus was isolated from the heart's blood, but the stomach was normal, with the exception of a small hemorrhagic area in the serosa, representing the site of injection.

A similar operation was performed on another dog, who also recovered, and after two weeks seemed to be perfectly normal. Because of the statements in the literature that alcohol seems to be a predisposing factor, we introduced 50 c.c. of 50 per cent. alcohol into the stomach of this dog on several successive days, by means of a stomach tube. A twenty-four hour broth culture of the same organism was then poured over the meat which was eaten by the dog at a single meal. The animal became ill, with spells of vomiting for two days, but later recovered and seemed to be as well as ever. One month after the operation this dog was given an intravenous injection of a twenty-four hour culture, and was killed the next day. A careful examination of the stomach at autopsy showed only a few punctate hemorrhages beneath the mucosa; otherwise it was normal.

In most of the cases thus far reported streptococci have been found commonly in pure culture, rarely associated with other organisms such as the staphylococci, or the bacillus coli communis. Muenter<sup>9</sup> reports a case in which the pneumococcus was apparently the causal organism.

As early as 1893 Pilliet<sup>10</sup> states that according to Straus and Schillon the infiltration of the stomach wall, and especially the connective tissue of the submucosa, is caused by death or injury to the mucous membrane, through which streptococci may gain access to the depths. He further states that in producing the disease, experimentally, mineral acids or organic acids are of no avail, since they lead to the formation of a sear or only to a hemorrhagic infiltration of

the wall. By introducing 5 gm. of zinc chloride (1-10), over a period of three days, into a rabbit, he succeeded in causing the formation of a scar and edematous swelling of the mucosa and submucosa, so that the thickness of infiltrate was 0.1 to 1 cm. No bacteria were demonstrable in sections. His conclusion is that acute fibrinous infiltration of the stomach wall is brought about only with the caustic solutions, such as zinc chloride and not with coagulating substances. This, according to him, is the first step in the production of phlegmonous gastritis. Our own experiments along these lines were negative, in the case of a dog. Kleiberger's patient<sup>11</sup> received 3.5 gms. of potassium iodide in three days, and this author believes that the iodide entered the stomach through defects in the mucosa and set up an inflammatory process which later led to phlegmonous gastritis. Bossart (loc. cit.) believes that idiopathic phlegmonous gastritis has its points of origin in the flat epithelium at the cardiac end of the oesophagus, and that this region is especially favorable for the localization of streptococci.

More recently, Cheinisse<sup>12</sup> has directed attention to the unappreciated occurrence of acute gastritis in infectious diseases. He has encountered several cases of erysipelas and mumps in which the gastric symptoms dominated the clinical picture and could be explained only by assuming a localization of the specific infectious process, the erysipelas or the mumps, in the stomach. Cheinisse had a case of phlegmonous gastritis in 1909 which developed in the course of an apparently mild erysipelas. Baird<sup>13</sup> also reports a case which ended fatally shortly after the development of facial erysipelas. Vasilevsky<sup>14</sup> also believes that phlegmonous gastritis is a secondary complication in the course of some general infection such as erysipelas. In his case the erysipelas spread to the mucosa of the mouth, pharynx, oesophagus and stomach.

We are inclined to believe that local injuries are not an important factor in the causation of this condition, but rather that it represents the localization of an organism, analogous to subcutaneous phlegmon, and to be explained on the basis of the anatomy of the organ, and possibly thrombosis of the vessels of the submucosa. As bearing upon the rôle of focal infections in the production of phlegmonous gastritis, the case of Schwarz<sup>15</sup> is of interest. In his case the infection apparently spread from the tonsils, which were swollen and ulcerated. In the latter, as well as in the fauces and in the peritoneal exudate, numerous streptococci were found. Schwarz believes that a portion of the cases, at least those with unknown sources of infection, might be explained as due to infection from the tonsils. It should also be remembered that this condition is practically never diagnosed except at autopsy. It would be well to bear in mind that this condition is a possible complication in acute infectious diseases and to suspect it whenever acute stomach symptoms develop, especially when ac-

companied by sudden pain in the epigastrium, and severe vomiting of material containing pus.

## Medical Progress.

### PROGRESS IN OPHTHALMOLOGY.

By EDMUND W. CLAP, M.D., BOSTON.

#### ETIOLOGY OF GLAUCOMA.

R. H. ELLIOT has written on the ætiology of glaucoma, discussing various theories. We quote him as follows. We cannot base our ætiology on the pathology, but on clinical observations tempered by a study of the changes produced both in the eye and in the organism by those conditions of life which may be causative of the disease. Glaucoma being a label for a large group of conditions, the distinctive feature of which is increased tension, must have a widely different ætiology in different cases. Once increased tension is established, every sign and symptom finds a ready explanation.

The different factors cited as causes of glaucoma may be brought under one or the other of two headings: (1) Those which influence the balance of secretion and excretion of the intra-ocular fluid. (2) Those which directly or indirectly determine a change in the vascular conditions prevailing within the eye. Taking up the more interesting observations, we have changes in the vortex veins. Ligature of these veins in animals produces increase in tension, but thickening and obstruction of these veins in glaucoma is rare. Disease of the vessels, brought forward as a cause, may usually be put down as a result, of the increased tension.

Schnabel in 1892 thought that cupping of the disc was due to an acute atrophy of the nerve itself. The lamina cribrosa was not pushed back by pressure, but pulled back by shrinking of the nerve. Small spaces were formed, and at length a large cup—a cavernous atrophy. But this cavernous atrophy has been met with in eyes that never have had increased tension, and no signs of it are found in most glaucomatous

globes. Disappearance of the cupping has been seen after an operation permanently reducing the tension. T. Henderson believes that a structural change in the pectinate ligament is responsible for an obstruction to the ready access of the aqueous fluid to Schlemm's canal.

Sclerosis of the pectinate ligament may offer an obstacle to free escape of aqueous, but it is universal as age comes on, while glaucoma is not very common. Intraocular pressure does not tend to rise as age advances. This theory does not account for shallowing of the anterior chamber nor closure of the filtration angle. The production of edema by action of acids or alkalis on the colloidal tissues of the body led Fischer to consider glaucoma an edema of the eyeball, in which the amount of water held by the hydropyllic colloids is increased by an abnormal amount of acid. But we do not find the swelling of the ocular tunic which the theory demands, nor the strength of acid sufficient to produce the effect.

Closure of filtration angle is caused by the base of the iris being pressed against the periphery of the cornea. Next the surfaces adhere from plastic exudate and the iris is firmly compressed so as to occlude the spaces which normally allow the free passage of fluid through the iris stroma. Finally atrophy of the iris comes on, and a drawing back of the iris when the ciliary processes retract. In congestive glaucoma, turgescence of the ciliary processes displaces their apices forwards and inwards, and carries the iris forward, and tends to jam its base against the cornea. In simple glaucoma, forward displacement of the iris is a result of the enlargement and advance of the lens. Closure of the filtration angle occurs at some stage in nearly all, if not in all, cases of primary glaucoma. Shallowing of the anterior chamber is associated with closure of the angle, and in itself favors a wider adhesion of the iris base with the cornea. When there is increased tension without much shallowing of the anterior chamber there is an altered aqueous which renders filtration slow and difficult. Priestley Smith sums up his views as follows: A shallow anterior chamber is a physiological condition of the time of life in which primary glaucoma arises, and is due partly to growth of the lens and partly to advancement of the lens by the prominent ciliary processes.

In an acute attack the turgid processes block up the circumferential space, and the vitreous is imprisoned behind the lens and drives it forward, and perhaps the swollen processes themselves drive forward the lens. Smallness of the eye is frequent in glaucoma, and the eyeball is fully grown somewhat before the rest of the body, while the lens grows larger as life advances.

Probably these changes are operative in the causation of all attacks of glaucoma. In the congestive attacks they are overshadowed by

evidences of the vascular storm. The incidence of glaucoma increases with advancing years, and may be attributed to: (1) enlargement of lens, (2) slackening of zonule, (3) thickening of pectinate ligament. Degenerative changes: (1) increase of volume of fluid secreted by the eye, (2) alteration in the nature of the secretion of ciliary body, (3) autogenetic intoxication. Risley says glaucoma rarely occurs in individuals in good general health, and LaGrange says such an eye is a sick eye in a sick body. Arteriosclerosis is probably not a factor; as far as high blood pressure is concerned, loss of vasomotor control in the body generally, and in the eye specially, plays a part in the causation of glaucoma. Females suffer from glaucoma more than males, in the proportion of about 57% to 43%. Heredity, too, plays a part. Smallness of eye, a want of normal development of structures about the angle of the anterior chamber, instability of nervous and vascular systems, conditions of environment, may all be considered here. Perhaps there is some connection between hyperopia and glaucoma, though it can occur in myopes. Mydriasis from drugs, exclusion of light, influence of violent emotions, and the effects of depressing diseases may give rise to increase of tension. Finally, febrile diseases and injuries must be included in the etiology of glaucoma.

#### INTRASPINAL TESTS AND MEDICATION.

Examination of the spinal fluid has attained great value in the diagnosis and the spinal route has aided in treatment. Ayer reports 160 cases of interest to the ophthalmologist. He finds this method most important, not in the plain cases of tabes or atrophy, but in early cases of slightly irregular or unequal pupils, perhaps with sluggish reaction, in early diplopia, suspected atrophy, etc. Of 40 cases of external ocular palsy, in eleven the tests were of prime importance, the palsy being the only sign. In 44 cases of primary optic atrophy there were found only 12 normal spinal fluids, and four of these tests were after antisyphilitic treatment. The outlook for the atrophies, if taken far advanced, is nearly hopeless; in early cases there is some chance. Argyll-Robertson pupils mean syphilis of the nervous system, but the spinal tests may show whether the disease is active, or stationary and degenerative only, or dead and quiescent. When irregular pupils are found, the importance of syphilis as an active factor can be determined.

Along this line is the work of Schoenberg, who has done experimental work on intracranial treatment of syphilitic optic nerve affections. His experiments show that serum introduced into the spinal canal does not reach the optic nerves. There is no doubt that spirochetes and not toxins alone, are the cause of syphilitic primary optic atrophy. The outer and the inner (ventricular) surface of brain, the outer sur-

face of the optic nerves, the perivascular spaces penetrating into the brain tissue and into the septa between the optic nerve bundles, form a system of spaces and channels filled with cerebrospinal fluid, and into this we must introduce our medication if we intend to reach the nervous tissue itself.

Schoenberg tried intravital staining in animals, and found that intraspinal or intravenous injection of the stain did not reach the optic nerves. The chorioid plexuses retain the stain in intravenous injections. Cranial intraventricular injections, without exception, gave the best results. The accepted view is that tabetic and parietic optic atrophy consists of a primary degeneration starting in the retina, while in cerebrospinal syphilis the degeneration is descending, often following an inflammatory process in or around the chiasm or optic nerve. Syphilitic and metasyphilitic changes then occur under two types—one mainly in the vascular interstitial tissue, the other mainly in the parenchymatous tissue (ganglion cells and fibers). The first constitutes cerebrospinal syphilis, the second tabes and general paralysis. More recent studies seem to throw doubt on the retinal origin of primary optic atrophy and that everywhere an exudative process precedes such a picture, but the spirochetes must play the important part. If these researches are confirmed, the importance of direct treatment is evident and must be intraocular so as to get at the microorganisms while they are in the nerve sheaths and before they migrate into the nerve bundles and between the fibers, and degeneration has set in.

#### TRAUMATIC HYPOTONY.

Treacher Collins treats of that form of hypotony occurring after contusions of the eyeball, in which no perforation of its coats has taken place. The duration of the diminished tension varies from a few days to several weeks, and in some cases it appears to be permanent. The author gives several cases, and discusses the probable causes at length under these headings: (1) Diminished secretion—(a) from nerve inhibition, (b) from vascular disturbance, (c) from epithelial damage. (2) Increased excretion—(a) through normal channels, (b) through new given channels.

We give his conclusions: That hypotony may be due to different causes, and more than one cause may be present in the same case. The cases of short duration are due to increased rate of excretion through expanded normal channels or possibly to some arrest of secretion from paresis of the vasoconstrictor nerves.

When of long duration, it may be due to the formation of new channels of exit from the anterior chamber, either from an internal scleral rupture or rupture of the pectinate ligament, the cutting off of the blood supply to the ciliary body from rupture of the anterior ciliary ar-

teries, or possibly detachment of the pars ciliaris retinae. If accompanied by extensive hemorrhage into the anterior chamber, either the canal of Schlemm has been opened up by internal scleral rupture, or the anterior ciliary arteries have been torn across from cyclodialysis. If a portion of the iris has disappeared, as though an iridectomy had been done, there has been cyclodialysis with rupture of the anterior ciliary arteries. If a translucent area appears after a time just outside the sclero-corneal margin, then there has been an incomplete internal rupture. If the anterior chamber becomes markedly deepened in the whole or in part of its circumference, there has probably been a rupture of the pectinate ligament and of the ciliary muscle, prolonging the angle of the anterior chamber outward.

If the lens is dislocated laterally and the retina detached, the vitreous humor has probably come forward into the circumferential space, and may have dragged the pars ciliaris retinae away from the pigment epithelium.

#### ANOMALIES OF ACCOMMODATION.

Duane considers anomalies of accommodation from the clinical point of view. He has observed the following: (1) The accommodation may be persistently below normal limit. (2) Accommodation normal in amount, but sustained only with effort and soon exhausted. (3) Sluggishness in changing from one accommodative state to another (inertia of accommodation). (4) The accommodation in the two eyes is not the same. (5) The accommodation lies persistently above the usual normal limit. Insufficiency of accommodation may be intermittent or constant, and transient or persistent. This condition occurs in at least 5% of our patients. It is not common before 15 or after 45. It may be due to undue rigidity of the lens or to weakness of the ciliary muscle. In the type due to premature sclerosis of the lens the accommodation drops in the normal fashion from year to year, but in any one year is always below the normal standard. The second type is due to pathologic conditions; it varies, often in a haphazard manner, even rising to normal at times. Mixed types probably occur.

The causes of the simple premature presbyopia are unknown, but the ciliary weakness has been found due to: (1) Toxic conditions from infectious disorders. (2) Nasal obstruction. (3) Neurasthenia and anemia from overwork, impaired nutrition, etc. (4) Vascular hypertension. Insufficiency of considerable amount may be called paresis, and one that is more complete a paralysis. Paralysis of accommodation is due usually either to poisons (cycloplegics) or to syphilis. The syphilitic (tabes, general paresis) paralysees are intractable and of bad prognosis and not yielding to treatment, though they may get well spontaneously. They are often unilateral, and usually, but not

always, associated with paralysis of the sphincter iridis. Non-syphilitic disease of the central nervous system has caused it, as also have traumatism, disorders of metabolism, eye strain and diphtheria.

In toxic and traumatic paralyses the lesion is usually peripheral. In syphilitic paralyses it is either peripheral, basal or nuclear. Unequal accommodation may be due either to lens or ciliary muscle. In syphilis, traumatism and poisons the sphincter iridis is affected too. Most of the other cases seem to be due to unequal rigidity of the lenses.

#### THE BLIND SPOT.

Gradle reviews what we know of the blind spot, beginning with Marriotte in 1668. The fibers from the retina around the optic disc lie in the periphery of the optic nerve, directly beneath the pia throughout its entire course.

In speaking of sinus disease, he says, the infection, the edema or other disturbing factor passes from the sinus periosteum through the diploic veins and lymph channels to the orbital periosteum, thence by continuity to the intracanalicular portion of the dura of the optic nerve, or possibly through the periosteal veins or dural veins, directly to the vein of Vossius.

If the dura alone is involved, a pressure is made upon the periphery of the nerve within the canal, and an enlargement of the blind spot will result. If the process extends farther and involves the central vein of Vossius, the neighboring nerve bundles will suffer. These are the papillo-macular bundles, and a central scotoma follows. In Gradle's view, when the optic nerve is involved in sinus disease the trouble is transmitted by the soft parts alone. The enlargement of the blind spot in an outward direction in malignant myopia is attributed to peri-papillary atrophy, of which the chorioidal signs can be seen, but the retina measured only by the perimeter. Gradle does not believe that medullated nerve fibers cause an enlarged blind spot. He mentions the relation of the blind spot to the field in glaucoma, and the fusiform enlargement above and below the vertical meridian in sympathetic ophthalmia. In eclipse blindness there has been found enlargement of the blind spot. Gradle says that tobacco or alcohol amblyopia is due to a toxemia of the bundles within the optic nerve itself, and that the relative central scotoma may or may not include the blind spot. The author gives his method of measuring the blind spot. He used a white screen with dark steel balls actuated by a magnet from behind.

#### DESICCATION OF NEW GROWTHS.

Clark has had success in using the desiccation method on epitheliomas about the eye, sarcomas, angiomas, moles, warts, xanthelasma, upus, pterygium, granular conjunctivitis and

corneal ulcers. Heat is employed just sufficient to desiccate the growth without carbonizing it. The heat is best generated by a high frequency electric current subject to accurate regulation. The author used a high speed static machine. Local anesthesia for the conjunctiva by a 4% cocaine solution; for the lids, infiltration with novocaine and epinephrin, is employed. A very fine needle in an insulated holder is just brushed over the tissue, but not usually thrust into it.

The depth of the desiccation depends on the time of contact and the driving power of the current. A minute growth or pigmentation, even on the cornea, may be desiccated without danger of going too deep, or part or the whole of an eyelid may be removed with precision. Cartilage and bone may be devitalized. After a growth has been converted into a dry mass, it is usually curetted or excised immediately, but sometimes it may be allowed to slough. There should be no bleeding. No sutures are necessary, and the cicatrix does not show a tendency to contract. Infection has not been observed, and the blood and lymph channels are sealed. The author compares this method with excision, radium and x-ray treatment, cautery, liquid air, etc., and after detailing many cases, gives the following conclusions:

Desiccation is good treatment for localized basal cell epitheliomas of lids and canthi, both from a curative and cosmetic standpoint. In advanced epitheliomas of these regions it may be a useful palliative treatment when operation fails.

The results in round-celled and melano-sarcoma have been good, but time enough has not elapsed to determine ultimate results. Success is assured in benign growths of the lids. Symblepharon usually does not follow desiccation.

#### GLASS WORKERS' CATARACT.

Robinson, who in 1903 and in 1907, wrote on cataract in glass workers, has a new report on this subject. In a majority of his patients, the opacity began in a characteristic way in the cortex of the lens at the posterior pole. It is just under the posterior capsule, often irregularly disc-shaped and by oblique illumination brass colored. As the haziness spreads it clings to the posterior capsule so as to be saucer-shaped and often presenting an irregular network. From the posterior pole the opacity gradually spreads and the ripe cataract has a pearly hue. In the later stages it is not to be distinguished from an ordinary senile cataract. The author believes this type of cataract not to be a secondary one, as operation usually gives good vision and shows no fundus disease. The original report gives a lengthy description of the exact nature and conditions of the work done by different workmen. The author could not get the opportunity to examine all the men in his district so that his figures are probably too low. In these factories about 400 men are em-

ployed, and he found 40 with cataracts. In the cases where the onset could be ascertained, two-thirds began before the fiftieth year. The average time from beginning failure of sight up to disablement was about three years. Both eyes are almost always affected. In another series of cases, where there is much incompleteness in the data, of men over fifty and disabled from various causes, of 114 men, 37 had cataract; and there is no record of those under 50. Dr. Legg found in 513 furnace workers 22 cases of cataract, and not more than two of these could have been included in the former statistics. In a large factory employing 4000 hands, one-half are exposed to glare of furnaces and one-half not. Each half contributes about equally to the cases of ordinary sickness, treated by a Sick Club, but all the cases of cataract found have come from the half who are exposed to the furnace glare. The frequency of cataract varies in proportion to: (1) the heat, (2) the degree of exposure, (3) the length of time each day and the number of years the men are exposed. The author discusses the physics of light at length and concludes that ultra violet rays do not cause the damage nor do the luminous rays, but the heat rays are to blame. Of course, protective measures, especially glasses, have been advised, but not much used as yet. Sir William Crookes has had glass made that will cut out nearly all the infra red rays (not our present "Crookes' glass"), but it is not yet practical, as it does not transmit enough luminous rays.

### Book Reviews.

*Refraction of the Human Eye and Methods of Estimating the Refraction.* By JAMES THORINGTON, A. M., M. D. Emeritus Professor of Diseases of the Eye in the Philadelphia Polyclinic and College for Graduates in Medicine. Philadelphia: P. Blakiston's Son and Company.

The author states that this work is an amalgamation of his previous works "Refraction and How to Refract," "Prisms" and "Retinoscopy." These have been combined and modified to produce a book for beginners in ophthalmology. The book certainly covers the ground in a comprehensive and entertaining manner. With the exception of a few tests of historical interest only, Dr. Thorington gives all the methods of detecting and correcting errors of refraction and muscular balance and all the theoretical knowledge necessary to a good understanding of these subjects.

The book is eminently practical and we recommend it to all students of refraction. There is a good chapter on the fitting of spectacles, etc. There are 344 illustrations—twenty-seven colored. The book is finely gotten up, with flexible covers.

*The National Formulary.* Fourth Edition, published by the American Pharmaceutical Association. 1916.

The first edition of the American National Formulary was issued in 1888. This fourth edition, representing the third revision of the original, is prepared by the committee on National Formulary of the American Pharmaceutical Association and is published by the latter's authority. It is official from September 1, 1916. After an historical introduction, a series of tables, a chapter on sterilization and various special notices, the text is divided into two parts, the first presenting the standard formulary, the second consisting of preparations dropped from the pharmacopoeia but retained in the form of an appendix. The passage of the Federal Food and Drugs Act has made the National Formulary a legal standard and placed it on a par with the Pharmacopoeia. Its source is a sufficient guarantee that it is worthy to meet the responsibility thus placed upon it.

*A Manual of Surgical Anatomy.* By LOUIS BEESLY, F.R.C.S., Edin., and T. B. JOHNSTON, M.B., Ch.B. New York: William Wood & Company. 1916.

For many years Treves' Applied Anatomy has been the standard work on this important subject in the English-speaking profession. The publication of this new Scottish work on the same subject by the demonstrators of anatomy in Edinburgh University, inevitably challenges comparison with their distinguished predecessor, but in point of fact should be more fairly judged on its own merits. It is not intended that the work should encroach on the domain of operative surgery, so that details of technique are largely eliminated. The book is compact and has been brought within the reasonable compass of 537 octavo pages by the omission almost entirely of descriptions of amputations of the limbs. With reference to tubercular disease of the bones and joints, especial attention is given to the anatomical relations of the diaphysis and the adjacent epiphysis to the capsules and synovial reflections of the corresponding joints. The book is conveniently divided into five sections dealing respectively with the two extremities, the head and neck, the abdomen and pelvis, and the thorax and vertebral column. It is well illustrated with 164 figures, many of which are colored and a few are radio-graphic. The authors are to be commended for the general adoption of the B. N. A. terminology. That they have not done so consistently is a creditable evidence of British conservatism and common sense. This new work is to be welcomed as a genuine contribution to the field of surgical anatomy in which it should fill a valuable place beside its English predecessor.

# THE BOSTON Medical and Surgical Journal

Established in 1812

An independently owned Journal of Medicine and Surgery published weekly under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, NOVEMBER 30, 1916

## EDITORS

**SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, Manager,

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

## THE NEED FOR PSYCHIATRISTS IN THE ARMY AND NAVY.

In all the talk of preparedness it should not be forgotten that the medical branch of our military organization should be so equipped as to be able to meet any demands upon it, especially those demands arising out of the peculiarly stressful conditions incident to actual warfare. Of course we are accustomed to think of the army or navy doctor as first of all a surgeon. He must be capable of handling the cases as they come from the front,—the gunshot wounds, the bayonet stabs, the burns and the broken bones. Stationed at a lonely post in time of peace, far away from any civilian physician, he must be prepared for any emergency,—to reduce a dislocated shoulder, to operate upon a strangulated hernia or a gangrenous appendix.

To their credit he it said that the personnel of the medical branch of our service is com-

posed of men who are amply equipped, not only as surgeons, but as internists. When we consider that every one of them has had, besides his four-year medical course, a year, at least, in a general hospital and a year of post-graduate work in the Army or Navy Medical College, their high average of efficiency is explained. And yet there is one branch of medicine which it would seem should be recognized as too complex and too important to be left entirely to men who necessarily must be able to give only a small part of their studies to it. We refer to mental disease. It is hardly possible for the Army or Navy surgeon, speaking generally, to acquire a sufficient knowledge of psychiatry to do justice to such cases of mental disorder as develop naturally and sporadically under service conditions or burst into being endemically under the nervous strain of battles. The frequency of mental disease among soldiers and sailors, as well as the necessity for its adequate study, is becoming appreciated and has been written on by Bouchard, Granjux, Hanry, and Rayneau in France; Borovikoff in Russia; Schultze and Hense in Germany; and White, Richards, Smith, King, Woodson and Sheehan in the United States. It has been only comparatively recently, however, that the necessity for establishing a field hospital for the care of such cases has been understood. The first hospital of this kind was organized in Harbin during the Russo-Japanese War.<sup>1</sup>

The desirability of having their medical officers better equipped for the handling of such cases is, at present, recognized by both branches of the service; and at the Government Hospital for the Insane every winter the Superintendent, Dr. White, gives a series of lectures to the members of the Army and Navy Medical Colleges. Also it has been the custom for some years past to detail one man from each service at the Government Hospital for the Insane, to study mental disorder for two years at a time. An officer recently detailed there, Capt. Edgar King, has published an interesting account of his studies of mental disease in soldiers.<sup>2</sup> In this, among other things, he calls attention to the fact that one-fifth of all soldiers discharged are discharged on account of mental disability.

But striking as is the prevalence of mental disease among our soldiers and sailors in times

<sup>1</sup> Military Surgeon, 1910, Vol. xxxi, pp. 177-194.

<sup>2</sup> Mental Disease and Defect in United States Troops. By Capt. Edgar King, U.S.A., M.C. Bulletin No. 5, War Department.

of peace, we must remember that this would be greatly increased during war. Such, at least, has been the experience of the nations now in conflict, as evidenced by the many reports of mental and nervous affections which reach the medical press. Injuries of the central nervous system, due to the wind of explosives, hysterical aboulias developing in the heat of battle, hypomaniacal outbursts in protracted battles, nerve injuries by missiles, malingering of mental symptoms to escape active service, hypochondriasis and neurasthenia in recruits,—all these and many more will call for the intervention of the trained neurologist and psychiatrist. As White says, "A man may be quite able to get along all right,—in fact, to perform his duties with marked efficiency in time of peace,—who would break completely under the stress of war. This has long been realized as true of the physical, but we must begin now to realize it as equally true of the mental, especially as the game of war comes more and more to be played with brains."

---

### MODERN CONTROL OF DRUG ADDICTION.

A RECENT sensational raid in Boston, whatever its justice and merits, has served to direct public attention anew to the prevalent evils of drug addiction and to modern methods and efforts for its control. The operation of the federal and state anti-narcotic laws has enabled a more active campaign against this evil and has gone far towards minimizing it. Unfortunately, however, although these laws largely control the supply of narcotic drugs, they do not provide for the care of drug habitués who are liable to become a miserable and dangerous class of derelicts in the community and who deserve control, treatment and restoration of health as much as any other group of unfortunate patients.

In view of the admitted incompleteness of action of existing drug legislation, there was appointed in Massachusetts, in July, 1916, a special commission to investigate the use of habit-forming narcotic drugs and to suggest measures for dealing further with the situation. The first public hearing of this commission was held on October 9 and the second on October 30. The

members of the commission are Dr. Frank G. Wheatley, Dean of Tufts Medical School, Mr. Herman C. Lythgoe, Director of the Division of Food and Drugs of the Massachusetts State Department of Health, and Mr. Abraham C. Weber, Assistant District Attorney of Suffolk County. A similar commission is working on the same problem in New York.

At the first hearing of the Massachusetts commission, the chief questions discussed were the advisability of giving the Board of Registration in Medicine the power to discipline or disestablish members of the medical profession upon the production of evidence of unprofessional conduct, evasion or violation of the provisions of the anti-narcotic laws; and the enactment of legislation taking away from druggists the right to fill prescriptions for narcotics and placing it in the hands of a state department. The latter measure was particularly advocated by Dr. Irwin H. Neff of the Norfolk State Hospital.

At the second hearing the chief topic of discussion was the advisability of establishing separate institutions throughout the state for narcotic drug habitués. It is estimated that there are 110,000 such habitués in Massachusetts and 2,000,000 in the United States.

The subject of the control of drug addiction was also considered at the annual meeting of the American Medical Editors' Association, in New York, on October 26. At this meeting Dr. Frank S. Abbott of California emphasized the importance of isolation of narcotic drug patients, and recommended the standardization of national and state laws regarding habit-forming drugs.

In another column of this issue of the JOURNAL we are glad to publish an article by Dr. Rubin of the Norfolk State Hospital, dealing with various aspects of the situation as outlined above, and especially with modern methods for the control of drug addiction. This article derives a particular pertinence from the contemporary work of the Commission on Narcotic Drugs, and at this time should arouse the especial interest of the profession, whose attention is directed to it for this purpose.

---

DECLINE IN NUMBER OF BRITISH MEDICAL STUDENTS.—It is stated in a recent issue of the *British Medical Journal* that in 1913 the total number of medical students entering Cambridge University was 116; in 1914, 64; in 1915, 41, and in 1916, 25.

## TUBERCULOSIS INVESTIGATION AT FRAMINGHAM.

IN a recent issue of the JOURNAL we noted the plan of the National Association for the Study and Prevention of Tuberculosis to conduct a three-years' experimental investigation of the disease in some selected locality. On November 10, it was announced that the town of Framingham, Mass., had been selected for this purpose, for which a fund of \$100,000 is available. Dr. Donald B. Armstrong, assistant secretary of the Association, was executive chairman of the committee which made this selection after a careful canvass of many towns in Massachusetts and New York with a population of approximately 10,000. The reason for the selection of Framingham instead of its closest rival, Johnstown, N. Y., was on account of the medical supervision of public schools, the district nursing association and the excellent hospitals maintained in the former town. The committee in immediate charge of the work to be undertaken is composed as follows: Dr. Edward R. Baldwin of Saranac Lake, N. Y., president of the National Association for the Study and Prevention of Tuberculosis, and chairman of the special committee of investigation; Dr. Charles Hatfield of Philadelphia, secretary; Dr. Lee K. Frankel, sixth vice-president of the Metropolitan Life Insurance Company; Dr. Stephen J. Maher of New Haven, president of the Connecticut Anti-Tuberculosis Association; Dr. Homer Folks of New York City, secretary of the New York State Charities Aid Association; Dr. William Charles White of Pittsburgh; and Dr. Arthur K. Stone, president of the Massachusetts Anti-Tuberculosis Association, and chairman of the state trustees of hospitals for consumptives.

The work will be an experiment in community cooperation, and, if successful, will form a basis for similar anti-tuberculosis work throughout the United States with a view to the ultimate total eradication of the disease. The work will be remedial, preventive and educational.

"It is planned to give a three-months' course of lectures and clinics to the doctors of the town and to have adopted a standard diagnosis.

"Every open case of tuberculosis here will be located and cared for either in the homes or hospitals and every effort will be made to keep them from being exposed to the disease. If a person can afford to pay for treatment he will

be expected to pay, but if unable, all expenses will be paid from the fund.

"There will also be a campaign of education through the schools, churches and newspapers. In every way possible the people of Framingham will be roused to the importance of looking after their health. It will be recommended that every person in town be examined by a doctor at least once a year.

"If the experiment proves successful and the commission will have expended all the available funds, another \$100,000 will be given toward the work by a Boston philanthropist."

Dr. Allan J. McLaughlin, Massachusetts Commissioner of Health, in discussing the project, is reported as follows:

"Obviously, the demonstration is of tremendous importance to Framingham, to the State of Massachusetts and to the world at large. If a success, it will point out the way to the control and, possibly, the eradication of this great world scourge.

"It is not only a fight against tuberculosis, but also a constructive general health and disease preventive program that is contemplated. It ought to make Framingham the healthiest and safest spot on the face of the earth in which to live.

"The success of the work depends entirely upon the complete cooperation of the local and state authorities. The Framingham people have assured the national committee of their earnest and continued support. Needless to say, the State Department of Health will give every possible assistance to the work, and earnestly hopes it may be a genuinely successful fight against unnecessary and wasteful disease."

This experimental investigation is obviously one of extreme interest and its prosecution in a Massachusetts town will afford particularly favorable opportunity for observation of its progress by physicians throughout the state as well as for direct cooperation by local members of the profession.

## ACUTE PSYCHOSES OF WAR.

It may be accepted without necessity for verification that the intense emotional strain associated with warfare causes acute exacerbations of some of the milder psychotic and border-land cases which were able to get along unnoticed under the less stringent requirements of civil life. Thus, cases of arrested dementia precox, the neuroses and psychoneuroses, cyclothymia and high-grade imbecility may all be found

among recruits who have been mustered in without any suspicion that such conditions existed.

Dr. Arturo Morselli, consulting neurologist to the First Army of Italy, in a lecture to the Royal Medical Academy of Genoa, classified the mental cases which he believed originated directly from the emotional excitement of battle into seven kinds, all of which he thinks have a basis of "asthenia." The term is, of course, extremely general in its English connotations. These varieties of mental disorder he gives as acute asthenia, hysteria, depression, stupor, hallucinations, confusional states and maniacal excitement. Probably, according to the American method of classifying mental disease, we should call the first two of these conditions psychoneuroses. The depression and the excitement we should expect to find in individuals of a manic-depressive make-up, that is, the extroverted type, while the introverted type would show the stupors and the confusional states. Morselli speaks of transient hallucinations, which, of course, may arise in persons with feeble psychic resistances, that is, imbeciles, psychopaths and constitutional inferiors, from stimuli inadequate to others normally constituted—small amounts of alcohol, slight infections, mild fevers, abstinence from food for short periods, and unusual emotional stress.

The modern idea of such deviations from the normal is that they are the expression of an underlying biological defect. To the experienced observer, such cases would not, as a rule, give rise to any great difficulty in diagnosis when they presented themselves for enlistment. The life history, as given by the applicant himself, is very suggestive to the alienist, his record with the Binet-Simon, Yerkes-Bridges, Healy, Fernald and other tests, his neurological examination, all supplemented by several days' observation of him, might result in the elimination of much rotten timber which later on becomes a problem to the army in the field.

The solution which suggests itself is to have a trained psychiatrist available for consultation at every recruiting station, especially in times of war.

PREVALENCE OF DISEASES IN THE UNITED STATES.—The weekly report of the United States Public Health Service for November 10, 1916, states that during the month of September there were, in the state of Washington, 87 cases of typhoid fever, 24 of smallpox and 10 of poliomyelitis.

## PROGRESS OF POLIOMYELITIS.

DURING the past week the various epidemics of poliomyelitis throughout the United States have rapidly declined. The weekly report of the United States Public Health Service for November 17, 1916, gives the following totals of cases from July 1 to November 9 as follows: New Jersey, 3,983; Pennsylvania, 1,790; Massachusetts, 1,771; Connecticut, 881; Minnesota, 849; Illinois, 805; Michigan, 449; Maryland, 309; Iowa, 212; Rhode Island, 206; Indiana, 177; Maine, 114; South Carolina, 113.

During the first 26 days of November the number of cases reported in Massachusetts was 171, making a total of 1885 in this state since January 1, 1916. Of these, 480 cases, with 124 deaths, have been in Boston. The monthly bulletin of the Massachusetts State Department of Health for October contained the following statement relative to the disease in this commonwealth during September:

"Cases of anterior poliomyelitis continued to be reported from all parts of the state. The number for the month was 626, making a total of 1,016 cases reported to the Department since the first of January.

"The peculiar distribution of cases noted last month still continues. In the Pittsfield-North Adams area the disease has come to a standstill in Adams and North Adams, while in Pittsfield there has been a gradual increase in cases, with a further centre of infection developing in the neighboring town of Dalton. In the Greenfield-Montague area but two new cases were reported. No cases were reported from Dudley and Webster, while Worcester reported but seven cases.

"At present there are two important areas of infection, one is in the Connecticut valley with Holyoke and Springfield as a centre. In Westfield and Northampton the disease has remained quiescent. The other important area of infection is located in the metropolitan district, which last month had a low incidence of the disease. During July and August Boston reported but eight cases, while in September the number increased to 172, and many of the surrounding communities also began to report cases.

"The infection along the Merrimac River, mentioned in last month's summary, has continued active, and has extended to North Andover, Boxford, Georgetown, Newbury and Salisbury.

"The September reports were as follows: Boston, 172; Holyoke, 59; Springfield, 39; Pittsfield, 32; Malden, 18; Cambridge, 14; Newburyport, 13; Quincy, 12; Somerville and Everett, 10 each; Amesbury, Lynn, Medford, 9 each; Beverly, Chicopee, North Adams, Revere, 8 each; Worcester, 7; Adams, Auburn, Braintree,

Chelsea, Dalton, Dedham, Haverhill, Lowell, Newton, South Hadley and Warren, 5 each; 4 cases each in Brookline, Milton and West Springfield; 3 cases each in Belmont, East Bridgewater, Fall River, Leominster, Milford, Weymouth and Winchester; 2 cases each in Billerica, Blackstone, Boxford, Brockton, Danvers, Fitchburg, Hamilton, Ludlow, Melrose, Monson, Newbury, North Attleborough, Sangus, Tisbury, Waltham, West Newbury, Winthrop and Woburn; 1 case each in Agawam, Barnstable, Bernardston, Bourne, Bridgewater, Conway, Dover, Foxborough, Framingham, Gloucester, Great Barrington, Greenfield, Hadley, Hudson, Hull, Leicester, Lexington, Lunenburg, Mount Washington, Mansfield, Marblehead, Marlborough, Methuen, Middleton, Nahant, Nantucket, North Andover, North Reading, Northampton, Norwood, Otis, Oxford, Palmer, Plainville, Princeton, Rockland, Rockport, Salem, Southbridge, Southwick, Stockbridge, Stoneham, Stoughton, Swampscott, Taunton, Tewksbury, Wakefield, Watertown, Wellesley, Westfield, Westford, Westminster, Weston and Williamsburg.

**"Characteristics.**—Up to the present time the cases of anterior poliomyelitis have continued to affect the usual age group. The majority of the cases are under ten years of age. This characteristic is one of the most constant features of the disease. Any theory that will explain this infection must satisfactorily explain the constancy with which this age group of the population is attacked.

**Mortality.**—From the incomplete records received by this Department, the anterior poliomyelitis fatality rate for September was higher than for August. There were 626 cases reported, with 136 deaths; giving a rate of 21.6, as compared with the fatality rate of 15.2 for August. A more detailed analysis of these rates will be made when the final and complete figures are received from the Secretary of State's office."

The Boston clinic for the after-care of recovered cases of poliomyelitis, which was announced in last week's issue of the JOURNAL, was opened on November 21 at the Children's Hospital, under the charge of Dr. William Hall Coon, executive officer of the Harvard Infantile Paralysis Commission, under whose auspices and that of the State Department of Health the clinic will be conducted. It will be held from 9 to 11 A.M. on Tuesdays, Thursdays and Saturdays. Further plans will be later announced. The surgeons engaged in the work of the clinic at the Children's Hospital are Dr. Frank R. Ober, Dr. Arthur T. Legg, and Dr. Hale Powers. The first session of the Boston clinic was attended by 25, and the second by 15 patients.

## MEDICAL NOTES.

**CHANGES IN COST OF DRUGS.**—Report from New York on November 15 notes further recent changes in the cost of drugs, the chief variations being an increase in the cost of quinine and a decrease in that of the salicylates.

"Heavier buying of quinine, from both domestic and foreign sources, has resulted in an announcement by manufacturers of an advance of five cents an ounce to a bulk basis of 55 cents for the sulphate in 100-ounce tins. Buying for next spring's requirements has absorbed quite a quantity of the spot goods, and an advance in cinchona bark has also had some influence on the price. A revision was announced in cinchonidin alkaloid crystals to 59 cents in 100-ounce lots; cinchonidin sulphate to 35 cents an ounce; quinidin alkaloid to 93 cents an ounce; cinchonin alkaloid to 23 cents an ounce; and cinchonin sulphate to 15 cents an ounce. All minor salts of quinine are irregularly higher. Opium, morphine, and codeine have remained firm at the recent advance, \$1.50 to \$1.00, respectively, while menthol has become somewhat firmer on better demand. The salicylates and other phenol derivatives have been reduced sharply by first hands, and resale lots can again be had for less than the maker's price. Camphor is quieter and prices remain steady. The demand for opium from domestic consumers is unimportant, but export takings have been somewhat heavier. The gum is quoted at \$12 per pound in cases and jobbing lots, while the powdered and granular are maintained at \$13 per pound."

**SALE OF SPURIOUS NEOSALVARSAN.**—Report from New York on November 15 states that the Federal Grand Jury at Newark, N. J., has recently indicted two citizens of Toronto, Canada, for being concerned in an attempt to defraud the Government by smuggling salvarsan and neosalvarsan into this country. In the possession of these men was found, also, a quantity of spurious neosalvarsan which, upon analysis, proved to consist of starch and sodium chloride. It appears that during the summer of 1916 an extensive sale of this spurious product was made throughout the middle Western states and as far east as New York. The alleged neosalvarsan is put up in packages imitating the English and German brands.

**NEW YORK DEATH RATES.**—According to figures given out by Acting Health Commissioner John S. Billings, the death rate for the past week was 35 lower than the corresponding week of last year. This decrease in the death rate is equivalent to a saving of 38 lives.

The mortality of the following diseases was lower last week than during the week ending

November 13, 1915. The contagious diseases, the diarrheal diseases, cancer, tuberculosis (all forms) and diseases of the nervous system.

There were only seven deaths from poliomyelitis in the entire city during the past week. There was a material increase in the mortality of heart disease, lobar pneumonia and Bright's disease.

The total number of deaths reported during the week was 1315, equivalent to a rate of 12.28 as compared with 1324 deaths and a rate of 12.63 for the corresponding week of 1915. In the group under one year of age there was no saving of life. On the contrary, one more death was reported among infants last week than during the week ending November 13, 1915. In the group between one and five years, 24 fewer deaths were reported. The reduction of mortality in this group was due to the fewer deaths from contagious diseases, diarrheal diseases and broncho-pneumonia. In the group over 65 years of age there was a slight increase of mortality.

The death rate for the first 46 weeks of 1916 was 13.96 as compared with 13.91 for the corresponding period of last year. This is equivalent to a drop of .01 in the difference between the accumulative rate since last week. According to Dr. Billings, this is really a remarkable showing in view of the 2000 deaths from poliomyelitis this summer and the 2000 deaths during the grip epidemic last January.

**AMERICAN ACADEMY OF DENTAL SCIENCE**—A monthly meeting of the American Academy of Dental Science was held recently in Boston. Papers and discussions were presented by Dr. Charles R. C. Boardman, Dr. Charles F. Painter, and Dr. Kurt J. Thoma.

**MASSACHUSETTS STATE NURSES' ASSOCIATION.**—The autumn meeting of the Massachusetts State Nurses' Association was held in Boston on November 11. In the forenoon separate meetings were held by the League of Nursing Education and the Private Duty Nurses' League. At the general meeting in the afternoon the following papers were presented:

Education and Training for Public Health Nurse. Miss Anne H. Strong, A.B. and R.N., Assistant Professor Public Health Nursing, Simmons College, Boston.

Plan of the A. N. A. for reorganization. Miss Esther Dart, R.N.

Necessity for change in the Registration Law for Nurses. Miss Mary M. Riddle, R.N., Chairman State Board of Registration for Nurses in Massachusetts.

Presentation of "New Bill," endorsed by the Legislative Committee of the Massachusetts State Nurses' Association, the Council of the Massachusetts State Nurses' Association, and the "Joint Board of Registration in Medicine and Nursing."

#### EUROPEAN WAR NOTES.

**COMMENDATION OF GERMAN MEDICAL STAFF.**—In the issue of the *Münchener Medizinische Wochenschrift* for October 3 is quoted the following army order issued by the German crown prince on August 18, commending the sanitary staff of his army for fidelity in its discharge of duty. "The severe fighting before Verdun has placed upon sanitary service a task which could be efficiently discharged only if every individual performed his duty with the truest fidelity and unwearied devotion. I therefore express my warmest gratitude to all who, during the six months' fighting, have been called upon to care for the wounded and sick, to nurse them and to mitigate their suffering. Especial recognition is due to the surgeons, assistants and litter-bearers of the troops, and the entire personnel of the sanitary companies, who, gallantly and undismayed by the severest fire, stood faithfully beside their fighting comrades and manifested devotion to service in the most self-sacrificing manner. The consciousness of having been the saviours and helpers of their brave comrades in the hour of peril is for them and their faithful work the finest reward."

**WAR RELIEF FUNDS.**—On Nov. 25 the totals of the principal New England relief funds for the European War reached the following amounts:

Belgian Fund .....	\$178,320.91.
French Wounded Fund .....	155,213.93
Armenian Fund .....	127,143.85
German Fund .....	74,972.87
French Orphanage Fund .....	70,898.00
British Imperial Fund .....	68,720.36
Surgical Dressings Fund .....	57,994.06
Polish Fund .....	49,095.33
Permanent Blind Fund .....	28,173.86
Italian Fund .....	27,268.54
French Phthisis Fund .....	7,309.50

#### BOSTON AND NEW ENGLAND

**WEEK'S DEATH RATE IN BOSTON.**—During the week ending Saturday noon, November 25, the number of deaths reported was 263, with a rate of 18.04 against 14.63 last year. There were 37 deaths under one year of age, against 30 last year, and 82 deaths over 60 years of age, against 68 last year.

The number of cases of principal reportable diseases were: diphtheria, 34; scarlet fever, 25; measles, 8; whooping cough, 11; typhoid fever, 5; tuberculosis, 61.

Included in the above were the following cases of non-residents: diphtheria, 10; scarlet fever, 9; tuberculosis, 13.

Total deaths from these diseases were: diphtheria, 5; measles, 1; whooping cough, 2; tuberculosis, 21.

Included in the above were the following deaths of non-residents: diphtheria, 2; tuberculosis, 4; whooping cough, 1.

**HOSPITAL REQUESTS.**—The will of the late Elizabeth Claffey of Boston, who died on October 7, contains a bequest of \$100 to St. Elizabeth's Hospital.

The will of the late Sarah C. Winn of Cambridge, Mass., who died on October 3, contains a bequest of \$1000 to the Nantucket Cottage Hospital.

The will of the late Mrs. William Binney, formerly of Providence, R. I., contains a bequest of \$3000 to the Sharon Sanatorium.

**HARVARD SURGICAL UNIT.**—On November 20 a new contingent of the Harvard Surgical Unit sailed from New York for England on the Cunard steamship *Andania*. This contingent consists of twenty nurses and the following six physicians: Dr. Francis W. Palfrey, Boston; Dr. Paul Hector Provandie, Melrose, Dr. Forrest Fay Pike, Melrose; Dr. Kendall Emerson, Worcester; Dr. Henry B. Potter, Wakefield, R. I., and Dr. Chauncey N. Lewis, Boston. It will relieve the members of the unit now on service at Hospital No. 22 of the British Expeditionary Force in France whose term expires on December 9.

**BOARD OF HEALTH OF PAWTUCKET, R. I.**—The recently issued annual report of the City of Pawtucket, R. I., records the prevalence of reportable diseases for the year 1915 as follows: diphtheria, 125 cases with 9 deaths; scarlet fever, 61 cases with 2 deaths; typhoid fever, 10 cases with 8 deaths. A case of leprosy, confined at the detention hospital, died in March, 1915.

### Miscellany.

#### MASSACHUSETTS STATE DEPARTMENT OF HEALTH.

##### RÉSUMÉ OF COMMUNICABLE DISEASES FOR OCTOBER, 1916.

**PREVALENCE.**—In spite of the excessive number of cases of infantile paralysis reported during the current month, the total number of cases of communicable diseases reported to the Department is considerably lower than the total for the corresponding month last year, and only slightly higher than the total for the previous month of this year. All of the diseases, with the exception of anterior poliomyelitis, smallpox and mumps, show a marked decrease over last year's figures for October, especially diphtheria, typhoid, and whooping cough.

**SMALLPOX.**—Cases of smallpox appeared in Lee and Great Barrington during the month of October. Its origin was apparently a missed case which occurred back in August, imported from another State. During the months of August, September, and October, nine cases in all have occurred. An interesting fact is that in only one of these instances is there a history of vaccination having been performed, and in this case it did not take and was not repeated.

**ANTERIOR POLIOMYELITIS.**—Based on estimates from the incomplete records received, the fatality rate for anterior poliomyelitis for October bids fair to be a little lower than that for September. The fatality rate for September was 24.7.

It will be noted that there is an increase of 80 cases of infantile paralysis in October over the num-

ber credited to September, making a total of 703 cases for October. This increase has been largely in the Metropolitan area. Boston heads the list with an increase of about 57; Quincy with one of 33; and Cambridge with one of 22. The disease still persists in the western part of the State, but a diminution in intensity in that section is apparently perceptible.

Following is a list of towns in which infantile paralysis has appeared for the first time during the month of October: Andover, Amherst, Athol, Attleboro, Belchertown, Cheshire, Deerfield, Dennis, Easton, Ercmont, Grafton, Halifax, Hatfield, Holbrook, Hopkinton, Longmeadow, Ipswich, Manchester, Mashpee, Natick, Northboro, Northbridge, Swansea, Templeton, Walpole, Wenham, Westwood, Warwick, Whitely, Wilbraham, Wilmington.

**DISTRIBUTION.**—All Communicable Diseases: Total cases Sept., 1916, 3130; Oct., 1916, 3260; Oct., 1915, 4550.

Case rate per 100,000 population: Sept., 1916, 83.0; Oct., 1916, 86.0; Oct., 1915, 120.6.

**COMMON DISEASES.**—*Diphtheria*: Total cases Sept., 1916, 470; Oct., 1916, 620; Oct., 1915, 1225.

Case rate per 100,000 population: Sept., 1916, 12.4; Oct., 1916, 16.4; Oct., 1915, 32.4.

*Hemlock*.—Total cases: Sept., 1916, 175; Oct., 1916, 250; Oct., 1915, 361.

Case rate per 100,000 population: Sept., 1916, 4.6; Oct., 1916, 6.6; Oct., 1915, 9.6.

Cities and towns which have exceeded their endemic index:\*

North Attleboro .....	(1) 13
Malden .....	(15) 22
Belmont .....	(0) 6
Webster .....	(2) 9
Ludlow .....	(0) 10
Westfield .....	(2) 14†

*Tuberculosis*. The number of cases of tuberculosis, all forms, reported for October, 1916, shows a falling

\* Endemic index signifies the average rate for each of the reported cases per 100,000 population. The index is calculated by dividing the town for each month by a certain number of cases. The number is then ascertained after the sum of the cases for each month is divided by the number of months. The index is then multiplied by 100 to obtain the endemic index. The index indicates the cases reported during the current month.

† Nine cases reported in the City of Boston.

off over those of the previous month, and a still greater decrease over the figures of a year ago. Part of this, at least, may be ascribed to a better system of "weeding out" cases reported more than once to this Department.

*Tuberculosis, pulmonary.*—Total cases: Sept., 1916, 62; Oct., 1916, 53; Oct., 1915, 732.

Case rate per 100,000 population: Sept., 1916, 15.9; Oct., 1916, 14.3; Oct., 1915, 19.4.

*Tuberculosis, other forms.*—Total cases: Sept., 1916, 58; Oct., 1916, 51; Oct., 1915, 85.

Case rate per 100,000 population: Sept., 1916, 1.5; Oct., 1916, 1.4; Oct., 1915, 2.3.

*Rare Diseases.*—Anthrax was reported from Woburn (1), and Dartmouth (1).

Cerebrospinal meningitis was reported from Chleopoe (1), Clinton (1), Lawrence (1), Lowell (1), Mattapoisett (1), Worcester (1) and Boston (5).

Dysentery was reported from Newton (2), Worcester (1), and Boston (16).

Dog-bite (requiring antirabic treatment) was reported from Great Barrington (1).

Pellagra was reported from Leominster (1), Monson (1), and Boston (1).

Septic sore throat was reported from Fall River (1), Amherst (1), Freetown (1), Lynn (1), Georgetown (1), Haverhill (1), and Boston (1).

Tetanus was reported from Lowell (1), Dartmouth (1), Lawrence (1), and Salem (1).

Malaria was reported from Fall River (5), and Wellesley (1).

Trachoma was reported from Leominster (2), Bridgewater (1), and Boston (2).

### UNITED STATES CIVIL SERVICE EXAMINATIONS.

#### DENTAL INTERNE (MALE).

The United States Civil Service Commission announces an open competitive examination for dental interne, for men only, on December 13, 1916. From the register of eligibles resulting from this examination, certification will be made to fill a vacancy in this position at \$600 a year, with maintenance, in Saint Elizabeth's Hospital, Washington, D. C., and vacancies as they may occur in positions requiring similar qualifications, unless it is found to be in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion.

The department states that it reserves the right to terminate the appointment at the expiration of one year of service if it is deemed advisable to do so.

In addition to many interesting cases presented, the dental interne is given an excellent opportunity for study and for doing experimental and research work in the pathological, histological, and other laboratories of the institution.

Applicants are required to be graduates or senior students of regularly incorporated dental colleges, and applications will not be accepted from persons who have graduated for more than two years. The names of senior students will not be certified for

appointment until they have furnished proof of actual graduation.

Statements as to training and experience are accepted subject to verification.

Applicants must be unmarried.

Age, 20 years or over on the date of the examination.

No sample questions of this examination will be furnished.

This examination is open to all men who are citizens of the United States and who meet the requirements.

Persons who meet the requirements and desire this examination should at once apply for Form 1312, stating the title of the examination desired, to the United States Civil Service Commission, Washington, D. C. Applications should be properly executed, excluding the medical and county officer's certificates, and filed with the Commission at Washington in time to arrange for the examination at the place selected by the applicant. The exact title of the examination, as given at the head of this announcement, should be stated in the application form.

#### PHYSICIAN (MALE).

The United States Civil Service Commission announces an open competitive examination for physician, for men only, on December 13, 1916. From the register of eligibles resulting from this examination, certification will be made to fill vacancies in this position in the Indian and Panama Canal Services, and vacancies as they may occur in positions requiring similar qualifications, unless it is found to be in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion.

The entrance salaries in the Indian Service range from \$1000 to \$1200 a year, and in the Panama Canal Service are \$1800 a year.

As the supply of eligibles resulting from recent examinations has not been equal to the demand, qualified persons are urged to enter this examination.

Applicants must be graduates of or senior students in recognized medical schools. The names of such senior students will not, however, be entered on the eligible register in the event they pass the examination, until they have furnished proof of actual graduation.

Statements as to training and experience are accepted subject to verification.

Applicants must have reached their twenty-first, but not their fortieth, birthday, on the date of the examination.

Applicants must be in good health, and must attach to their applications a statement showing the number in their family dependent upon them that will require accommodations at the Indian School or Agency in case they receive appointment.

No sample questions of this examination will be furnished.

Applicants must submit to the examiner on the day of the examination their photographs, taken within two years, securely pasted in the space provided on the admission cards sent them after their applications are filed. Tintypes or proofs will not be accepted.

This examination is open to all men who are citizens of the United States and who meet the requirements.

Persons who meet the requirements and desire this examination should at once apply for Form 1312, stating the title of the examination desired, to the United States Civil Service Commission, Washington, D. C. Applications should be properly executed, including the medical certificates, but excluding the county officer's certificate, and filed with the Commission at Washington in time to arrange for the examination at the place selected by the applicant. The exact title of the examination as given at the head of this announcement should be stated in the application form.

## Address.

### PREPAREDNESS FOR HEALTH.\*

By HAVEN EMERSON, M.D., NEW YORK,

*Commissioner of Health.*

YOUR yearly meeting to pay a debt of gratitude to those who made possible a gentler art of diagnosis, a quicker and safer skill in treatment and cure, has brought forth such tributes that I may safely leave the honors earned as they appear upon the record.

How suitable is our place of assembly, this generous and spacious building, the centre from which the guiding hand will direct the hospital family, the storehouse of priceless inventories of physicians' labors, the custodian of still unexplored treasures certain to bring forth gifts at the open sesame of the diligent student, broad in scope and with a view to future usefulness far beyond the imagination of the founders of this great educational institution.

To mobilize the knowledge and service of today is a privilege no less than to advance bit by bit the borderline of facts. And here we see provision for the one, and opportunity for the other. To my mind the best hospital is the one which succeeds in keeping the largest number of people out. To prevent the little disorder of today from becoming the serious operative risk of tomorrow, is an ideal to which that

greatest of all parts of a hospital, the clinic or dispensary, is devoted. But why wait until the patient comes to complain? Why not entice them to come to libraries, lectures, friendly personal visits, such intimate consultations for advice as have made the name of family physician, village minister, and parish priest beloved the world over?

Many of the big troubles the patients bring to your doors have their little beginnings in carelessness, misinformation, lazy habits, weak character and self-indulgence; and when you have set them on their feet and returned them home with a God-speed, you are not rid of them unless you have taught them while you have treated them.

The hospital of the future—and surely none by its past has so well earned the right to be among the greatest in the land for all time as this one—will have on its records and to its credit a life of histories marked *Case not admitted; sickness prevented by education.*

"To be used; that is the sublimest thing we know." So the gentle David Grayson inadvertently described the wish and hope of the servants of the common good who enjoy their work for the work's sake.

It is by cooperation and not merely by competition; by the persuasion of helpful ideas and not with destruction of things or people; it is in being for a principle and not by being against persons that the spirit of preparation and patriotism is developed in a community.

Preparedness; to make ready beforehand, to make ready for some particular purpose or service, to put things in suitable order, to be in a

\* Ether Day Address. Delivered upon the occasion of the opening of the Moseley Building at the Massachusetts General Hospital, October 16, 1916.

state of readiness, to adjust, to adapt,—this is the plan of the prudent citizen. Disagreement upon this is impossible, at least to the accidental.

For what, then, shall we be in readiness? To what shall we adjust ourselves? What shall be the nature of our preparations?

The answers will be as various as the ambitions of each one of you. In this great household of relief, this home of the helping hand, the privilege may be allowed me to take it for granted that at the moment you think of and feel with one accord the overwhelming call to make this country not only a place for freedom in religious observance and freedom of speech, but a land free from the burden of preventable disease.

"Preventable" is a word to conjure with, for no sooner is the true cause of sickness announced than the possibilities of prevention come knocking at the door. So we see the whole array of philosophy and science assailing the mountains of ignorance and returning from time to time with new trophies, called by the physicians the etiological factors, the specific or determining causes of disease. It is upon no short and easy path we are set out. The goal will continue to recede, the list of preventable diseases continue to grow, and by so much will our duty be enlarged.

If we can believe the somewhat dim records of early civilization, infectious and epidemic diseases were recognized then, and to meet them, racial and religious habits developed. Later, when mankind created an artificial environment and began to try his hand at wresting pleasures and comforts from resistant nature, there came upon him misfortunes created by his own personal habits. Again we find restraint and advice supplied by governments of church or state.

When man thereafter began to exploit not only nature but his fellow man, there sprang a host of new and insidious diseases which have made such inroads upon community and national existence in all lands that a voluminous body of civil law has been created in an effort to correct the health hazards of industry. With fair accuracy, then, we may divide the problem of health protection into:

1. The prevention of communicable diseases.
2. The correction of habits which determine or contribute to premature death.
3. The prevention of industrial hazards.

Under one of these three headings we can properly place most of the activities of the present-day campaign for health as a personal or a community problem. But bear with me a moment while I call to mind a preliminary which should be observed before attempting any new experiment. For a control and to establish a measure of results, we must know how many are there of us, how many are the annual recruits in the nurseries, and what the

afflictions are that draft so many to the army of the silent.

As the bookkeeper and accountant are the recorder and analyst of business transactions, so the registrars of births and deaths provide the means of assessing the results of public health administration.

What community is so dull as to be uninterested in its continued existence? Self-interest drives the sick patient to seek relief from pain and disability by appeal to his family physician. Shall not the village, city or state require at least an equivalent service of diagnosis, prevention and treatment for its various disturbances of community function, the destruction of its several members?

The merchant accepts our past experience as a guide to the need of future supplies; the salesman counts on publicity and education to create a demand for his wares. Shall our cities or our nation ignore their greatest asset, and fail to count the daily loss of lives as inexcusable? And yet—to our shame be it said—we, who claim to be a civilized nation, have still so cheap a notion as to life and death that we are without a national registration law or uniform state laws demanding the reporting of births and deaths.

In the councils of the world there is no record of the accomplishments of the United States as a whole in the field of preventive medicine and sanitation. True, honor is given to the great men of science produced here, but neither the birth rate nor the death rate of all the states is known. Are we so young, so satisfied with local accomplishments and excellences, that we can remain indifferent to the insufficiency of the very elements upon which constructive social statesmanship must be founded? Only 66% of the population of the United States lives in states where the registration of deaths is compulsory, and less than 31% live where registration of births is required. Only two-fifths of the area of the United States are included in the registration area for deaths, and but 10% of the land area of the United States is included in the registration area for births. Failing the national figures, which should have been available for the past hundred years, I may be excused if I use the records of New York City, which has just completed a half century of experience with a department of public health.

The yearly death rate has fallen from 29 per thousand to 14 per thousand of population.

Deaths from cholera, smallpox, yellow fever, typhus fever and malaria have all but disappeared from our records. In the first ten years there were 6260 deaths from smallpox. In the past ten years there were 7.

Deaths from tuberculosis, typhoid fever, puerperal fever, infantile diarrhea, diphtheria, and scarlet fever have shown a reduction of from 50% to 90% in this half century.

Since the incorporation of the greater city in

1898, the yearly death rate has been reduced 31%.

But best of all is the brilliant result of the scientific attack upon the infant mortality rate, which has fallen from 242 per 1000 living births in 1891 to 98 per 1000 births in 1915, and in the past five years from 170 to 98 per 1000 births. Whereas only 80% of the babies born in 1898 lived through their first year, now more than 90% survive. When this saving of lives was begun, there were those whose lack of confidence and information did not carry the conviction that this baby saving was an ultimate benefit to the community. Thanks to the data now available, we can answer with courage and certainty that the saving continues right up to the school age, and that the babies saved are the worth-while lives. The deaths were not inevitable and merely postponed a few months or a year or two. If the death rate of 1866 had prevailed in 1915, we should have lost in New York City last year 88,000 people who are now living.

The details of the methods by which these results were obtained in New York City, as in other cities and states here and abroad, need not concern us. This is not a year to dwell upon past victories, but to take thought lest in the onrush of events we find ourselves complacently satisfied with our successes, while our neighbors and, in terms of national existence, our competitors, may soon be striding past and beyond.

Remember that while there are the thousands killed in Europe in battle, more people are killed by preventable disease annually in this country than the annual loss of any nation in the present war.

Let us rather face the record and plan for our own more creditable future. To pick out three typical failures, we may properly consider why we still lose our thousands from tuberculosis, alcoholism, and among industrial workers.

Out of 75,000 deaths a year, we lost 31,700 from causes which are largely, if not wholly, preventable. Last year, in New York City, with a total population of 5,602,841 and a total death list of 76,193, there were 10,249 deaths from tuberculosis, and 1597 deaths admitted to be due directly to alcohol, and, as all pathologists and physicians in general hospitals or private practice know, the recorded deaths from alcohol represent but a fraction of the deaths really attributable to this drug, if not as the sole factor, as a contributory or determining cause.

There were 2596 deaths from diphtheria, scarlet fever, measles and whooping cough, and may I in parenthesis ask you to note that this is our annually recurring number, and is larger by more than a hundred than the total deaths from poliomyelitis in our recent epidemic.

Preventable accidental deaths numbered 2509, exclusive of deaths from violence and homicide and suicide.

We still lose 13,866 children under a year of age.

If we count at least 10 cases of sickness or temporary disability for each of the deaths above listed, we reach a total of 317,000. Evidently there is sufficient work ahead to keep us upon the tiptoe of endeavor.

In tuberculosis the first defect in control comes when the physician fails to make an early diagnosis. This failure must be shared equally by the patient and the private practitioner. One hardly ever sees an early case of pulmonary tuberculosis in our colored population. They are childlike in their optimism, and they neglect even the simplest precautions. They fail to obtain medical advice of any kind until seriously disabled. They must be taught to seek advice earlier,—a need worthy of a great leader.

When the state sanatorium for incipient tuberculosis was first opened at Raybrook, N. Y., early cases were sent only by a few physicians in some of the large cities, and this state of affairs persists to a serious degree at the present time, so that it is apparent that patients must call the physician earlier and the standards of diagnosis must be raised before we can make maximum use of our present knowledge as to the arrest of the disease. Perhaps the solution will come through a habit of annual or semi-annual medical examination of everyone, and such a habit would justify the time, attention, and small cost involved, if for no other reason than that many a case of tuberculosis would thus be noted and be promptly put in the curable class.

Twenty physicians of the Health Department examined 20,357 food handlers last year and found 1 in 1000 suffering from pulmonary tuberculosis. When 1116 private practitioners, for pay, examined 26,300 in the same industrial group, they found 1 among 3700 tuberculous.

There was a similar and equally serious discrepancy in the incidence of venereal diseases, as reported by the two groups of physicians. The Department of Health physicians discovered, among the 20,357 food handlers examined, 111 syphilites and 22 cases of gonorrhea. The private physicians discovered, among the 26,300 food handlers examined, 7 syphilites and 5 cases of gonorrhea. Of the 5 cases of gonorrhea, all but one were reported by the examining physician of a large railroad corporation.

There is much food for thought in these results. The clinical material under observation was as nearly uniform in the two groups as can well be imagined. The examining physicians of both groups were, in the main, graduates of the medical schools of New York City.

In the case of the private practitioner there was the opportunity of a new and considerable source of income, and remuneration in fair proportion for the time consumed, and there was the same responsibility to detect disease as is assumed when a patient calls at a physician's office frankly complaining of sickness. The food

handlers considered themselves healthy when applying for examination.

The Department physicians, drawn from the same professional ranks, working on a salary, were responsible for a methodical performance of a set task under the supervision of trained diagnosticians, and they discovered proportionately 3.7 times as many cases of pulmonary tuberculosis as the private physicians. And to make it quite clear to you that the Department physicians, working at the occupational disease clinic and not trained as specialists in tuberculosis, were well within the mark, I must remind you that there are a little over seven cases per 1000 of the population in the city at large.

The query is inevitable; are private practitioners in the by and large, ready to detect disease in people who assert that they are healthy? Is the public sufficiently protected at present, if the symptoms of disease must be declared by the patient before it is named and treated by the physician?

As patients come to the tuberculosis dispensaries in New York City, the story is too often told, that the family physician has been treating for weak lungs for some time, but has never examined the bared chest or made a microscopic examination of the stained sputum. Unless such stories become a thing of the past, the community will revolt against medical services upon a personal basis. Such medical service is disgraceful and should not be tolerated. Excusable, perhaps, before 1882, when Koch proved the tubercle bacillus to be the cause of the disease, or before 1819, when Laennec demonstrated tubercular disease of the lungs by physical examination of patients; but generations of physicians have been taught since then, and still there are physicians who practise tongue and pulse medicine blissfully oblivious that diagnosis is capable of treatment as an exact science.

With our present knowledge, secondary cases of tuberculosis in a family are a needless waste of life. We know the cause, and enough of the mode of transmission to prevent infection, but it is easier to treat from an office chair by pen and pill, than to become the actual teacher and family instructor in the home, weeks and months on end, so that the facts known are used by the people exposed.

Are we forever to await the call of the sick patient before giving service? Must we sit by and see that for every 1000 children living in certain blocks of every city, so many will become infected with a preventable disease, as to which we know the specific cause and the means of transmission?

If New South Wales has found it possible to have every person examined by competent physicians, every infected person isolated or so controlled at home as to break the endless chain of transmission, and thus to bring pulmonary tuberculosis to an end in that commonwealth

and prevent the entrance of infected people in the future, is there not a service worthy of an effort here? Is it good government, or utter social neglect to permit incompetent physicians to continue to practise years after they have ceased to learn, or have become incapable of applying the facts upon which prevention of disease must rest? Is not the public interested?

Shall we continue to permit the construction and occupancy of buildings in every city in the country, and in many of our rural regions, unfit for human needs and certain to lend themselves to the development and perpetuation of sickness?

And with syphilis it is no different. Eight per cent. of push-cart peddlers have been found to be syphilitic; 25% of the children and adults admitted to a great orthopedic hospital show positive Wassermann reactions.

Here, again, we are confronted with the dual failure. The spreader of the disease fails to obtain diagnosis and treatment that will put an end to his particular infection, and the physician fails to report the disease and to insist upon such personal habits and persistence of treatment as will alone prevent danger to others. Have we the courage to adopt an honest and rational program such as has recently been established by law in Western Australia, and has been in force in Denmark for the past ten years? This law holds the patient and the physician equally responsible,—the patient to obtain immediate treatment and persistent care until cured, the physician to report the case, teach, caution, and treat the patient, if necessary at public expense, and under restraint, until the possibility of transmission is at an end.

Why allow competition to determine the distribution of medical services? Why is there one physician to three hundred and fifty-six persons in Hampstead, and one physician to five thousand five hundred and eighty-two in Shore-ditch in London? Why is the proportion in New York City, one to five hundred and eighty-nine in Manhattan and The Bronx, and one to fourteen hundred in Queens? After a man or woman has been taught through the endowments of elementary schools, colleges, medical schools and hospitals, and has arrived at the age of from 25 to 30, so far unproductive, are we to consider that the community owes them a living or that they owe the community a life?

Is competition for money to determine the future progress of the graduated physician, or is he to be a public servant drilled and trained to play a most responsible part in our modern economic and social structure? Is the public need to determine their training, their location, and their income, or will these all be determined by the question of largest financial return? Physicians have committed themselves to a process of voluntary self-elimination, and society will not easily accept them now or in the future on the basis of individual competition for money,

which determines the number and distribution and capacity of other professional groups.

Shall the physician continue to be at the beck and call of the lady with a severe case of lack of occupation, and must he kowtow to the business magnate whose disease-breeding tenements are largely responsible for the consumption rate?

Shall the hospital be filled by those who want to go and can afford the price, or by those now waiting outside, whom the dispensary physician knows must lead a handicapped existence for lack of the very luxury of rest in bed, from excess of which my lady-do-nothing suffers? The wrong people are generally in hospitals. The selection is made more by means than by needs.

Shall the hospital retain the seclusion of its walled privacy and await the coming of the lame and fevered, or shall it become a high school for health, with extension lectures, a reference library on personal hygiene, a centre for organized consultation, a seat of preventive medicine?

We lose each year in New York as many lives from alcoholism as the devastating epidemic of infectious colds cost the City of New York last winter, as many as all the deaths from the epidemic of poliomyelitis, which has raised the whole Eastern coast of this country to a point of panic. And what is to be done, and what has been done to prevent these regiments and more from marching this year, as last, out of New York City to the graveyards? Education coupled with enthusiasm must not be mistaken for fanaticism. Legislation has never changed habits, but may follow a change in popular convictions.

To convince the people of this country that the use of alcohol internally is to their disadvantage would seem a simple matter to anyone with an elementary understanding of physiology, and the action of the anesthetic group of drugs.

What nurse or doctor who has had a hospital service, but has seen enough to make each one a permanent crusader for a non-alcoholized society? And yet we find physicians permitting the use, condoning its use, yes, prescribing alcohol with a freedom which cannot but make them pause and consider when the stories of the habitués come to their ears. So strong is the inertia of habits, so vast the momentum of large industries, that it will take years of teaching to wean our people from this, their worst dietary enemy. Must we wait for a national calamity to shock us into appreciation of the extravagance of our wasted lives? I think it is fair to say that no single thing would make so immediate a change in the whole list of causes of death in adults as the abandonment of the use of alcoholic beverages. Every group of preventable diseases in adults would show a diminution in incidence and in death rate. And

among children, too, it predisposes to various ills and weakens resistance to infections.

The education of public opinion and private habits is at present the only reasonable and promising measure at the service of the public health officer and the private practitioner in the effort to have the general use of alcoholic beverages, and the largest single cause of poverty and sickness, abandoned. Other habits also, as to housing, eating, personal cleanliness, recreation, etc., are certain to be modified by education, and in no other way.

As for the third class of general conditions in which we now fail to protect and prevent, the most recent and, in many ways, the most interesting as a public health problem, I shall ask you to note the widespread interest in tariff protection for the new chemical industry so extensively developed here from force of circumstances abroad. The halls of Congress were vigorously assailed in the interest of those who saw our opportunity, with governmental support, for the creation of a great and lucrative commerce at home and abroad. Protection is what they clamored for; protection of the chemical products against the keen and undoubtedly effective competition certain to develop when the bans are again removed from international trade.

More attention has been paid to the protection of industrial workers in Germany than anywhere else in the world, and the most recent report indicates that in the large chemical works in Germany, with the improved sanitary conditions, the sick rate is 54.9% of all employees per annum, with an average duration of sickness in each case of 17.8 days.

Among 185,820 employees in the chemical industry in Germany, in 1905, there were 163,522 cases of sickness, or 88% of all employees, with an average duration in each case of sickness of eight days.

Let the public take an active interest with the employer and the employee to see that the workman, who produces, is protected in this country; for it is obvious to the student of causes of death that the protective tariff upon a product may prove too high a price to pay for the doubtful security of carrying on with profit, trades which throw back into the community so many disabled workmen.

Are not the lessons of the day clear enough for us to see that the population of the wards of the hospital are the measure of our inefficiency?

How many admissions to the wards are sufferers from preventable defects? Strike off your hospital census those who have tuberculosis, or syphilitic lesions, and where is your overcrowded ward?

Count off the patients disabled from neglect of hazards of occupation, count those who pay their final reckoning for the life-long use of al-

cohol, and you see a dwindling line of beds and a short service in the operating room.

What the autopsy table is to the visiting physician and the surgeon, the hospital ward is to the health officer. There he is faced with his failures.

And why, you ask me, did I take the trouble to expose the failures or shortcomings of our present system, or lack of it, in view of the record of accomplishment of the past fifty years? Briefly, because the promise of the future cannot be fulfilled unless and until all physicians coöperate for the public good, as well as competing for private livelihood, and unless we make available for all, services in diagnosis, prevention and treatment of disease of the quality which now is doled out at a price for the few, given freely to the very poor, but unobtainable for people of moderate means.

One competent physician, in touch with and capable of using the resources of special diagnostic laboratories, and free to call consultants to his aid, will replace ten bunglers who at present survive only because the ignorance of their patients is denser than their own; will save more lives, abbreviate sicknesses, and at a cost far less than the tax for inefficiency now paid by the uninformed public.

Whether by organization, by endowment, or by state employment, it seems to me that there must come a change in the basis of medical practice.

Preparedness for health in any state or community requires for the prevention of communicable disease, accuracy in early diagnosis by the family practitioner, and such means and knowledge as to care and treatment as will shorten the period of communicability to the minimum, and limit the contact between the sick person and the rest of the community to those who are insusceptible or to places where the conditions of residence and supervision will prevent exposure.

Segregation of the infected individual in hospitals and sanatoria should become so universal for all communicable diseases that general hospitals and private establishments would serve the purpose now met chiefly at state and municipal expense. The pest house is the mediaeval conception which still clings about the idea of an isolation building. There should be a cheerful welcome and adequate provision for communicable diseases in every general hospital, with a medical and nursing service, capable of a technic equivalent to that of aseptic surgery, which can meet the modern needs of sanitary science and bring results in treatment and cure as brilliant and creditable to physicians as have been contributed by the surgeons. The public would be better protected, the treatment of infectious diseases would be improved, doctors and nurses would learn much which now they miss in a general service.

To alter habits which we know diminish resistance to disease, and limit the capacity for

intelligent endeavor and put a serious burden upon the community because of dependency in later life, we must teach the children of the schools, the parents in the homes, the men and women in the shops and factories, the patients and dependents in our dispensaries and hospitals, such simple truths as will encourage them to require and maintain clean, light, and airy living rooms, to avoid entirely the use of alcohol and patent medicines, to proportion their food to their needs, and to consider physical fitness not only a priceless inheritance, but its maintenance a national duty.

Before the inevitable victory over industrial disabilities can be complete, or the abatement of conditions which cause an annual loss from avoidable illness equal to the national debt, is accomplished, it must be borne in upon the minds of those who employ their fellow men that of more value than the product is the producer. The employers, the public and the employees are jointly responsible for conditions causing sickness among wage-earners and their families. The employer's legal responsibility is generally limited to the places of employment and working conditions. The public is responsible for community conditions common to all classes of citizens. The greater share of the burden as to cost and remedy lies upon the workman himself, but as he is unable to meet this responsibility single handed, it rests with the public and the employer to share with him the cost, and to determine the character of the service needed.

Thirty-five per cent. of the wage-earners of this continent must ask for public or private charity when disabled by disease. Shall it be said that we are so selfish, so short-sighted, so wasteful, that we prefer to pay a bill for damages, when health and time and economy are all to be had by paying for prevention?

The burden of giving free treatment to the victims of industrial hazards can no longer be carried by the medical profession. When the state, the employer, and the employee contribute to defray the cost of medical services for the prevention and relief of occupational disease, it will be reasonable to expect the medical profession to submit to a degree of periodic re-examination and continued compulsory training which, up to the present time, has existed only in the medical branches of our federal services. In the medical services of our federal government, re-examination is required periodically even to remain in grade, and advancement is only on examination. Attendance at post-graduate medical course periodically is compulsory.

In the Department of Health of the City of New York, advancement from grade to grade in the medical positions cannot take place without competitive examinations. Failure to earn average rating for efficiency for three successive quarter years of service results in the bringing of charges of incompetency against a physician..

Why allow all the glory to go to those who have reduced the death rates in the occupation least productive of national progress, the occupation of arms?

Between 1880 and 1916 the death rate among the native troops in India was reduced from 41 to 3.7 per thousand, and for British troops in India from 24.8 to 4.3; and similar results are within our reach in the vastly larger army of industry.

Of what avail to keep the policeman in perfect health if the families he protects from violence and theft are allowed to suffer from loss equally discreditable to representative government?

Scientific coöperative medical service promptly summoned and consistently obeyed; education in the ways of right living, from the training of the expectant mother, through the schooling of her child, and until the new home is started in the next generation; union of effort by the state, the employer, and the employee, to prevent wastage from occupational disease. Upon these principles of action must our social program for national service be built.

It is not a conflict with the popular clamor for a military and naval preparedness that I suggest, not a hindrance to commercial preparedness for greater national wealth, but a warning of the futility of both of these without the assurance that the first need and greatest asset of a nation, its health, should take the leading place in your thoughts.

In closing, may I quote from that sensitive student, that sharp analyst of society in the last century, Thomas Carlyle: "Men cannot live isolated. We are all bound together for mutual good or mutual misery as living nerves in the same body. No highest man can disunite himself from the lowest."

There is nothing so democratic as disease, no bond so strong as the appeal of suffering fellow men.

I beg of you to consider the merits of the philosophy of prevention of disease, a worthy development of modern medicine, and I ask you to devote at least part of your lives to the encouragement of preparedness for health.

**MASSACHUSETTS SOCIETY FOR MENTAL HYGIENE.**—The annual conference of the Massachusetts Society for Mental Hygiene will be held at Ford Hall, Boston, on December 13, 14 and 15. Among the speakers at the opening session will be Dr. Walter E. Fernald of Waverley, Dr. E. E. Southard of the Psychopathic Hospital, Judge W. T. Forbes of Worcester and Dr. F. E. Williams, chairman of the advisory prison board. Prof. W. H. Burnham of Clark University will preside and Lt.-Gov. Calvin Coolidge will be a vice-chairman. It is expected that proceedings of this meeting will be published in subsequent issues of the JOURNAL.

#### SPINAL FLUID SUGAR.\*

BY J. B. RIEGER, S.M., AND H. C. SOLOMON, M.D.,  
PSYCHOPATHIC HOSPITAL, BOSTON.

ESTIMATIONS of the reducing sugar content of the spinal fluids of 124 male, and 51 female subjects, in the main, psychopathic, gave values ranging from 0.050-0.090, or a grand average of 0.070%. The extremes, obtained in certain diabetic and inflammatory conditions are not here included. In general, the higher values have always been found in the more robust subjects, and aside from this, the range is the same in the psychopath as in the non-psychopath, in the male as in the female, and in the young as in the old.

The diagnoses made on these subjects are: general paresis, 47; dementia precox, 30; alcoholism, 22; manie-depressive insanity, 12; epilepsy, 6; diabetes, 6; juvenile cerebrospinal syphilis, 4; adult cerebrospinal syphilis, 5; arteriosclerosis, 4; pellagra, 2; tubercular meningitis, 1; hypopituitarism, 1; chorea, 2; tabes, 4; miscellaneous psychoses, 20; not insane, 10. On this basis the following values are remarkable: diabetes, 0.134-256%; pellagra, 0.90-0.102%; two of the more severe cases of cerebrospinal syphilis, 0.041-0.048%; tubercular meningitis, 0.026%.

Mestrezat<sup>1</sup> similarly reported low sugar values in the spinal fluids of individuals in whom there existed acute inflammatory processes of the meninges, and this circumstance he explained by assuming that the sugar in such cases is the substrate of the bacterial metabolism. That the values are uniformly high in general paresis, as reported by the same observer, could not be corroborated. Likewise, the figures 0.126-0.212%, obtained by Mott<sup>2</sup> in eight miscellaneous psychopathic cases, mostly dementia precox, in all probability can be ascribed to faulty technique.

The Bang micro-reduction method was at first employed, but owing to the wide fluctuations in the results obtained, it was abandoned for the Lewis-Benedict method, which proved more accurate in the hands of the authors. The fluids were obtained by lumbar puncture of the living subject.

\* Being contributed to the Massachusetts Society for Mental Hygiene, at its annual conference, held at Ford Hall, Boston, June 18, 1915. The first communication of this kind by the H. M. A. has appeared in the *Psychiatric Contribution to the Study of Delinquency*, to appear in *Journal of Criminal Law and Criminology*.

## AN OUTLINE OF THE ELEMENTS AND TREATMENT OF STAMMERING.\*

BY ANNE BRADSTREET STEDMAN, BROOKLINE, MASS.

(From the Out-Patient Department of the Psychopathic Hospital, Boston.)

IT is hardly necessary nowadays to state the general cause of stammering. With the exception of cases of structural defect, stammering is of purely mental origin. Defined, it is the expression in faulty speech of the neurotic temperament. Whether acquired or inherited, it is always there. There are no phlegmatic stammerers.

Therapy, therefore, must be based on this fact. It is the theory of some (Apelt among them) that a cure can be effected only by working from the inside out, that is, by giving all the attention to the frame of mind when speaking. Another method, practised by many teachers who are not physicians, disregards the mental element almost entirely; calls stammering a habit and approaches it through vocal exercises only—from the outside in.

It is true that stammering is largely a habit, and that cases have been found where it still persisted, even after the nervous condition had been eased, simply because the method of speaking, practised through a lifetime, had become mechanical. Also, in the case of children, the growing discouragement and accumulating fears can often be cut short by curing the habit alone.

But neither of these instances is drawn from the majority of cases by any means. Few can be so easily dismissed. The man with an obsession for zigzagging down the street in order to touch every lamppost, does not need lessons in walking through a meadow. He knows as much about walking as his instructor. Just so, the stammerer can produce perfectly normal consonants and vowels *when unembarrassed*. Practical treatment of the habit, vocal exercises, etc., are only half the battle. The treatment must go deeper, until it reaches the fear—the emotional disturbance that occurs under trying circumstances between the thought and its expression.

It is here that the training of a neurologist is required. Comparatively few specialists in speech defect are physicians, while the lay

teachers and so-called professors are legion. And yet stammering is as truly the province of the neurologist as any other nervous affection.

When, therefore, a layman undertakes to treat stammering, the field narrows for him. To reach the mental side of his case, he has to rely solely on the personal touch. He must be the patient's friend. The ideal plan is to go to the patient's home, walk with him; if a child, play with him; and if the patient is in school, interest the teacher of his grade in him. The recitation in school is nearly always the hardest thing a child has to contend with, and unless it is plainly too much for him he has to put up with it for the sake of his standing. But it is the duty of the speech instructor to see just how much strain a child can bear, and, whenever necessary, to get him excused from reciting until, with the treatment he is receiving, the ordeal shall have become less dreadful. Often, to tell a child who is constantly bracing himself for difficulties, that he need not do the things he dreads, is followed by surprise, gradual relaxation and a new perspective, which is a great help to normal speech. In the same way, other obstacles in the daily life of the patient can be surmounted.

In a public clinic this ideal plan is less feasible, and other means have to be found. In order to link the teacher's office (where, after the first, the patient finds himself very much at home) with the outside world, that is full of difficulties for him, the speech class is the next best thing.

Class treatment alone is usually most shallow. In every case it should accompany individual attention. But individual treatment, pure and simple, is apt to be too encouraging. Everything is not overcome, by any means, after the patient has learned to speak perfectly when alone with the teacher, whereas his speech in class is a pretty good indication of his progress at home.

In the speech class there is also the benefit to a reserved, rather lonely patient of contact with others, some of whom are more afflicted than he is himself. He discovers that his difficulties are shared; that, after all, it is possible to treat quite naturally the defect about which he had kept tensely silent all his life.

Then there is the opportunity in a class of this kind of reproducing every-day situations. It is not like a class in school. It is more informal and flexible. Everything is encouraged that tends to put the patient in a normal setting. The routine speech exercises of the teacher's office are here put into practice through storytelling, debate, and games that require conversation. No one joins the class until he is quite willing, and the most shy soon grow to like it.

It is, of course, more difficult to converse naturally in company on interesting subjects than to read or recite before one person, and patients whom the teacher has considered greatly improved frequently do less well when put into

\*Being Contributions of the Massachusetts Commission on Mental Diseases, Whole No. 157 (1916.15). The previous contribution (1916.14, 156) was by J. B. Rieger and H. C. Solomon, entitled "Spinal Fluid Sugar," BOSTON MEDICAL AND SURGICAL JOURNAL, December 7, 1916.

the class. There are also degrees of difficulty in class work. Making a prepared speech or joining in a formal debate is usually the hardest thing for every one. In some cases patients who had been speaking perfectly for months, when called upon to stand up and debate, lost complete control. Such occurrences, instead of being discouraging, are the teacher's opportunity. They show the weak spot in the patient's progress, and improvement from then on, though frequently hard won, is no longer superficial.

As to the elemental speech exercises, on which all such work is based, the methods used are various. They include many principles of singing, elocution, and phoneries, the most practical of which aim to correct a monotone by means of inflexion; rapid, nervous speech, by exercises in slowness; faulty breathing and misuse of speech muscles by training in breath control, relaxation, etc.

Unfortunately, these exercises have all to be overseen by the instructor. A patient cannot work upon them profitably at home. There is little result even when rules are followed quite conscientiously, because the patient is alone at the time, and those who stammer when alone are the rare exceptions. What he can do, and what has to be emphasized continually, is to use the newly acquired speech every day to everyone, just as he does in the clinic. If he does not slip into it easily, he should keep steadily at it until it becomes mechanical; but not every one has the character to do this.

In one sense, of course, the "character" of the patient plays a large part in his recovery. But the word is often misunderstood. Will, perseverance, ambition, are essential in the majority of cases. They make up the final third when a patient has been brought two-thirds of the way towards normal speech. But, as with other nervous cases, the stammerer is sometimes misjudged and thought to "give in" to his infirmity; whereas it is not a "trick" to be overcome by "trying." A change has to be brought about in the patient's attitude of mind; something has to relax, to let go before the force of ambition can even be appealed to. There are weak natures and careless ones, but my observation does not point to any greater lack of character on the part of stammerers than of any other class of people. Character—moral force, that is—is not synonymous with mental makeup, and it is the stammerer's mental makeup, for which he cannot be held responsible, which is at the bottom of his trouble. Cure the habit, but cure the mind as well.

**POSTPONEMENT OF TUBERCULOSIS SUNDAY.**—It is announced that the observance of Tuberculosis Sunday throughout the United States has been postponed from Dec. 3 to Dec. 10. The current week is being observed as "Open Window Week."

## FATTY DEGENERATIVE CHANGES IN THE PURKINJE CELL BELT OF THE CEREBELLUM IN EXHAUSTIVE INFECTIVE PSYCHOSES.\*

By EGBERT W. FELL, M.D.,

Assistant Physician and Pathologist, Elgin State Hospital, Illinois.

### ABSTRACT.

- I. Purpose of study: To determine, 1. Frequency of fatty change in the cerebellum in toxic condition; 2. Element most affected; 3. Extent of fatty change; 4. Relation to glia cell increase.
- II. Material used included various toxic and exhaustive, or infectious, conditions, controlled by arteriosclerotic and dementia precox material.
- III. Staining methods—Scharlach R. in frozen sections. Cresyl violet in frozen sections.
- IV. Recital of cases: 1. Clinical features; 2. More important post-mortem features; 3. Cellular changes in cerebellum.
- V. Summary of cerebellar cellular changes.
- VI. Discussion of changes: 1. Relation to duration of toxemia; 2. Relation of fatty to glia change; 3. Occurrence in other psychoses.
- VII. Conclusions.

RECENT advances in the physiology of the cerebellum, as reviewed, for example, by Mills and Weisenburg (*Jour. Amer. Med. Assn.*, Nov. 21, 1914), show that the function of this organ (probably represented by the Purkinje cells) is to maintain synergic control of movements. While certain portions seem more concerned with certain complex acts, localization is not sharply defined. The organ probably acts more as a unit than does the cerebrum. Exhaustive infective psychoses, presenting as they do, asynergic symptoms, as tremors, asthenia, atonia, ataxia, seemed to offer a good field for the study of cerebellar changes, and it was suggested that such a study in toxic states of various sorts would be of value in determining: 1, what element of the cerebellum was most affected; 2, the frequency of fatty change; 3, the extent of that change; and 4, its relation to glia cell increase.

The material at hand consisted of six cases autopsied at the Boston State Hospital by Dr. M. M. Canavan, and includes various toxic and exhaustive conditions.

*The Technical Method.* Frozen sections, made from formalin-fixed pieces of cerebellum, were

\* Read in abstract and illustrated at the Third Annual Conference of the Medical and Surgical Work of the Psychopathic Hospital, June 18, 1915. It is a contribution of the Massachusetts Commission on Mental Diseases, Whole No. 159, 1915-17. The previous contribution was by Thomas H. Haines (1914-15, 154), entitled "The Genesis of a Paranoic State," submitted to *Journal of Abnormal Psychology*.

stained with Scharlach R. and counterstained with hematoxylin, giving an intense salmon-red stain to the fat against a blue background. Continuous sections were stained with cresyl violet (Nissl's original stain did not give equally good results with the frozen sections).

CASE 1. Female, single, 66, was admitted Dec. 31, 1910, without a history. She was exhausted and jaundiced. There was a slight fullness over the left thorax. The radial pulse could not be felt. There was marked clouding of consciousness. On attempting to reply to questions her words could not be well made out. She appeared disoriented. She was restless; threw herself about in bed and attempted to get out. She may well have had hallucinations, and screamed at times without apparent cause.

She died Jan. 1, 1911, within a few hours after her admission, and autopsy was performed two hours later. The more important findings were: chronic fibrinous pleuritis, both sides; left hydrothorax with congestion of the left lung; chronic interstitial nephritis; bile capillaries distended, but the duct was patent; a small area of chronic external pachymeningitis over the inferior portion of the left ascending frontal convolution; pia uniformly thickened.

Microscopic examination of the cerebellum showed red staining of many of the small cells in the granule layer and of a large proportion of the small cells in the ganglionic area. Of the ganglion cells, about one-half were markedly affected, nearly all to some extent. The nucleus of many of the ganglion cells was distorted and dislocated, and with the cresyl violet stain tigroid bodies were found to be absent from a larger or smaller portion of the cell. There was little, if any, increase in glia cells.

CASE 2. Male, 39, single, was admitted Feb. 7, 1911, and died within twelve hours. Aside from his having been markedly alcoholic, nothing was ascertained as to his past. Respiration was difficult, and there was evidence of consolidation of the right lower lobe. His pupils were equally dilated, but the neurological examination, as far as it could be made, was otherwise negative.

He was disoriented and so confused as to be unable to give information. He was apprehensive, evidently as a result of hallucinations, and he spoke at one time of seeing rats.

Autopsy was performed 34 hours post mortem. There was found a right lower lobe pneumonia with an accompanying pleuritis. There was some sclerosis of the aorta and of the coronaries; the heart was large, weighing 535 grams. The liver was large and fatty; kidneys showed a chronic interstitial nephritis with an acute degeneration. There was considerable subpleural edema.

Microscopic examination showed a few red-stained small cells in the white matter of the cerebellum. Only an occasional cell in the granule layer was affected, but many of the small cells in the ganglionic zone. Of the Purkinje cells, about two-thirds were markedly involved.

In many nearly the whole cell was filled with granules, the nucleus being to one side, the cell misshapen, and with the cell stain, showed marked lack of tigroid bodies and the nucleus often staining quite indistinctly. There appeared to be little neuroglia increase.

CASE 3. A female, 53, married, was admitted May 9, 1911, with a history of having used alcohol moderately. Two weeks before admission, while getting dinner, she sat down, and it was noticed that she could not articulate well. The right side of her face was said to have been drawn down. She complained of a slight headache. When examined, her pupils were irregular, but reacted. There was only slight motion in the right side of the face, the upper part being involved as well as the lower, and the tongue deviated to the right on protrusion. The heart was enlarged to the left. There was no paresis of the extremities and the reflexes were normal. Urine sp. gr., 1035, and contained sugar. She appeared to be disoriented, but to what extent could not be well made out on account of her difficulty in articulating.

During her stay she had convulsive attacks, not accompanied by loss of consciousness, which involved only the right side of the face, the tongue and neck muscles. These clonic spasms lasted from 10 to 20 seconds, and at times occurred as frequently as every one-half to two minutes. She developed a left broncho-pneumonia with slight temperature, and died May 11, two days after admission.

Autopsy a few hours post mortem. More important findings: Hypertrophy of heart with fatty degeneration; fatty degeneration of kidneys; subpleural edema with atrophy of the convolutions in the frontal, pre- and post-central regions; irregular sclerosis of the basal vessels.

In the cerebellum the endothelial cells of the capillaries were more markedly involved than in the preceding cases, the red granules being larger. Two-thirds of the Purkinje cells had marked deposits of granules, and very few were not involved to some extent. In this zone the affected small cells formed an almost uninterrupted layer. With the cellular stain, disintegration of the tigroid bodies appeared quite marked. There was some increase in neuroglia cells in the Purkinje layer.

CASE 4. Female, single, 60 years of age. She had always been peculiar and irritable, was inferior mentally and had had a number of illegitimate children. In 1911, one year before admission, she began to fail physically, and examination by a physician showed that she had well advanced pulmonary tuberculosis. At about the same time she developed ideas of hypnotism and of influence.

On admission, Feb. 9, 1912, she was in a much weakened condition, and examination showed a marked involvement of both upper lobes. She was irritable and fault-finding, thought every one was against her, that she was being hypnotized and influenced. Her ideas do not appear to have been at all well worked out. She was oriented and memory seemed good.

She had a temperature from the time of her ad-

mission, often going to 102 or 103 in the evening.

She had attacks of diarrhea. Two days before her death, on Oct. 6, 1912, she developed a left femoral thrombo-phlebitis. She became dyspneic and moist râles were heard throughout the lungs.

Autopsy 3 hours post mortem disclosed advanced pulmonary tuberculosis; tubercles in the liver and spleen; tubercular ulcers in the ileum and colon; thrombosis of left iliac vein. Pia only slightly thickened; nothing else of note in the brain.

**Microscopic examination:** The cerebellum showed a moderate degree of change, confined mostly to near the ganglionic zone. About one-third of the Purkinje cells showed fat, but the deposit was nowhere very marked. Not many of the cells had nuclei dislocated, and with cresyl violet few showed internal disarrangement. There was some increase in glia in the ganglionic area.

**CASE 5.** A female, 42, divorced. Her father and mother were both alcoholic. In 1911, two years before admission, she had an operation for carcinoma of the uterus, and a year later began suffering from symptoms of an extension of the growth, pain, incontinence of urine, etc. About this time she began to hear voices, thought people were watching her, and that her food was poisoned. She reacted to these ideas.

When admitted, July 1, 1913, she was poorly nourished, but aside from evidence of extension of the carcinoma to the vesico-vaginal septum, there was nothing of importance found physically. She heard people outside cursing and saying that she was immoral. They were digging her grave. She was apprehensive and yelled out of the window at her tormentors. A little later the nurses seemed to talk among themselves about her and do other things to annoy her. She was oriented. She grew weaker, had vaginal hemorrhages, and died July 27, 1913.

Autopsy performed 3 hours post mortem showed a hydronephrosis from obstruction of the vesical orifice of the ureter by the carcinomatous growth. The pia was not thickened, and there was no sclerosis of the cerebral vessels. The brain substance was of a decreased consistency in both parietal regions.

The cerebellum showed considerable change in the capillaries, the red granules often being large. There was a fairly marked involvement in the granule layer and of the small and ganglionic cells in the Purkinje layer, about one-half of the latter being markedly affected. Considerable derangement of the internal structure of the ganglion cells and an increase in glia cells in this region was noted.

**CASE 6.** A male, single, 57 years of age, was supposed to have had a pulmonary trouble for some time, but for only a few weeks had been acting peculiarly. He was restless and irritable, tearing up his bedding at night without giving any reason for doing so. He was said to be untidy and resistful.

On admission, Feb. 7, 1914, he was very weak and poorly nourished. He was scarcely able to talk in a whisper, and had a cough. He had a

right scoliosis and a lordosis. There was dulness over both apices. He had a low, irregular temperature. Tubercle bacilli were never found in the sputum. He refused to coöperate, and when questioned would cover his head and refuse to explain himself. He seemed to be poorly oriented, but sense falsifications and delusions, while probably present, could not be brought out. He died March 13, 1914.

Autopsy, 46 hours post mortem. Carcinoma of upper and lower thirds of esophagus. Nodules over surface and peribronchial infiltration of right lung. Pia slightly thickened; amount of cerebrospinal fluid large.

The capillaries in the cerebellum were involved to very limited extent, and the changes were not very marked anywhere. In the ganglionic zone many of the small cells and about one-fifth of the Purkinje cells showed red granules. Many of the ganglion cells, stained poorly with cresyl violet, were misshapen and had the nucleus to one side. There was an increase of glia cells in the outer portion of the granule layer and in the ganglionic area.

These cases seem to possess sufficient clinical features to warrant including them in the exhaustive-infective group. Cases 1 and 2 are acute deliria; 3 diabetes with cerebral symptoms; 4, 5, and 6 are cases of longer duration in which the physical condition seems to bear a direct causative relation to the mental symptoms.

The changes found in the cerebellum may be summarized as follows:

1. *Capillaries.* A varying number of endothelial cells showed fine red granules, usually filling the whole cell. At times several adjoining cells were affected. The changes in the capillaries were confined largely to the granule layer and especially to the vicinity of the Purkinje cell belt, but a few of the vessels in the white, and also a few in the molecular, layer and in the pia showed affected cells in small number.

2. *White Matter.* An occasional cell, especially near the granule layer, showed red staining.

3. *Granule Layer.* A good many cells showed fine red granules surrounding the nucleus, the larger cells seeming to be especially affected. Changes were more marked toward the ganglionic zone.

4. *Ganglionic Zone.* Many of the small cells in this area (glia cells) showed red granules thickly set in the protoplasm, in some cases nearly all the cells being affected. The number of Purkinje cells affected in different cases varies from few to nearly all. Fine, intensely red granules were thickly set in the protoplasm, the collection being supra-nuclear or to the side when the nucleus was dislocated, as was often the case.

The infra-nuclear portion was seldom involved unless the whole cell was. With the cresyl violet stain, the Purkinje cells showed poor staining of the tigroid bodies correspond-

ing to the area stained red with Scharlach R. Also a varying amount of distortion of the cell body and nucleus was present.

Glia increase, especially in the Purkinje cell belt, was more or less apparent in chronic cases, these cells often showing fatty change.

5. *Molecular Layer* showed no fatty deposit, as a rule.

It is seen, then, that cell degeneration and fatty deposit is confined quite closely to the Purkinje cell belt, involving the capillaries and small cells, as well as the ganglion cells, especially in this region. In Cases 1, 2 and 3 (acute), the fat deposit involved a larger proportion of Purkinje and other cells, and the individual cells were affected to a more marked degree than was the case in Cases 4, 5, and 6 (chronic). In the more acute cases there was considerable internal disarrangement of the cell-structure, poorly stained areas in the chromatin, dislocation of the nucleus, but little, if any, glia increase. In the more chronic cases there were more shrunken and distorted cells, and there seemed to be an increase in glia cells that corresponded in a general way with the degree of Purkinje cell destruction. In Case 4 destruction was not marked, neither was the glia increased, while in Cases 5 and 6 both were quite advanced. The acute cases, then, showed in the Purkinje cell belt:

1. Marked fatty deposit.
2. Acute cellular changes.
3. No glia increase.

The chronic cases showed:

1. Less marked fat deposit.
2. Cellular change of a more chronic type, as shrinking, distortion, and complete destruction.
3. Glia cell increase, corresponding to the Purkinje cell destruction.

Of other cases examined, two, clearly of arteriosclerotic variety, but complicated by carcinoma, showed fatty changes in the cerebellum corresponding in every way with those described, but of less degree. The cellular destruction was quite marked in these two cases, as was the glia proliferation in one of them. In two precox cases there was no fat deposit in the cerebellum. In one case of Korsakoff's psychosis, fatty change in the cerebellum was confined to a few capillaries. A senile case showed changes similar to the arteriosclerotic cases. Two paretics showed no fat in the cerebellum.

So far as our investigation has extended we have found that:

1. Fatty changes of a type described in detail above occur in the cerebellum, especially in the Purkinje cell belt, in conditions which interfere with the nutrition of the brain, as arteriosclerotic brain disease, senile dementia, and in exhaustive infective psychoses.

2. The fatty changes are more marked in the toxic group than in others that we have examined.

3. The more acute the process, the more marked is the fat deposit.

4. In chronic cases the fat deposit may not be large, but as cell destruction advances, the number of glia cells increases.

5. This study demonstrates in a new way the great lability of the Purkinje cell region, of which there has been increasing evidence from other methods of investigation for many years past.

## THE YERKES-BRIDGES POINT SCALE; AS APPLIED TO CANDIDATES FOR EMPLOYMENT AT THE PSYCHOPATH- IC HOSPITAL.\*

By C. S. ROSSY, BOSTON.

*Intern in Psychology, Psychopathic Hospital.*

At the suggestion of Dr. Herman M. Adler, chief-of-staff, the Psychopathic Hospital has adopted the method of submitting to psychological examination every candidate for employment as clerk or attendant. It is the object of this paper to present the results obtained from the examination of the first sixty candidates.

*Candidates.* The candidates, both male and female, were referred to the Hospital by different employment agencies of Boston, with a few exceptions. The majority of them had attended grammar school, only 28% having advanced to the high school. Their ages varied from eighteen to fifty-five, the average age being twenty-five.

*Method.* After the candidate had applied for work to the superintendent of nurses, and his references had been verified, he was asked to report for a psychological examination. This examination consisted principally of the Yerkes-Bridges point scale, with the multiple choice,<sup>†</sup> and a few other supplementary tests given at the discretion of the examiner.

The point scale, devised in 1914 by Robert M. Yerkes and James W. Bridges, is a method for determining the degree of intellectual development. It comprises twenty tests, to each of which a certain credit is allotted. The subject is graded according to his reactions, with full, partial, or no credit; when the examination is completed, the sum total of these credits indicates his mental grading in percentage.

\* Read in abstract at the Third Annual Conference on the Medical and Social Work of the Psychopathic Hospital, June 18, 1915. Being Contributions of the Mass. Commission on Mental Diseases, Whole No. 160, 1915:18. The previous contribution was No. 159 (1914:17), by Egbert W. Fell, entitled "Fatty Degenerative Changes in the Purkinje Cell Belt in Exhaustive Infective Psychoses." BOSTON MEDICAL AND SURGICAL JOURNAL, December 7, 1916.

† A method devised by R. M. Yerkes for comparative study of individual reactions of human and infra-human subjects.

**Results.** From February to June, 1915, sixty candidates were examined. With the exception of two, who applied for position as clerk, all of the applicants solicited work as attendants. The following table shows the classification of these candidates according to their degree of intelligence:

TABLE I.  
CLASSIFICATION OF CANDIDATES ACCORDING TO  
MENTALITY.

Normal .....	63%
Slightly subnormal .....	17%
Intellectually inferior .....	20%

In the normal group, which includes only 63% of the whole, are found all applicants who obtained a score above 82 points, that is, who graded above the standard for the mentality of 15 years. (See "A Point Scale for Measuring Mental Ability," page 67.) Of these presumably normal candidates,

25 obtained .....	82-90 points
9 " .....	91-95 "
4 " .....	96-98 "

In the second group (17% of the whole), comprising candidates of slightly subnormal intelligence, are included those applicants who obtained between 76 and 82 points credit.

In the third group, we find 20% of the candidates. These graded below 76 points, and their reactions indicated intellectual inferiority. According to the norms of the point scale (see "A Point Scale for Measuring Mental Ability," page 67), these subjects did not attain a mental rating equal to that established for the intelligence of a 12-year-old child, namely, 77 points. Of the subjects included here,

7 obtained .....	60-69 points
5 " .....	70-75 "

It is noticeable that a history of alcoholism, immorality, or delinquency was obtained from many of these individuals.

The following charts represent, respectively, the distribution of mental grading and the distribution of education received by the applicants examined.

CHART I.  
DISTRIBUTION CURVE REPRESENTING GRADING OF 60 CANDIDATES  
FOR EMPLOYMENT.  
Ordinates—points scored; Abscissae—number of subjects.

CHART II.  
DISTRIBUTION CURVE REPRESENTING EDUCATION OF 60 CANDIDATES  
FOR EMPLOYMENT.  
Ordinates—school years; Abscissae—number of subjects.

Table II has been arranged to illustrate the variation in the responses of the sixty subjects to one of the twenty tests of the point scale, namely, Test 13, in which the subject is required to name as many words as possible in three minutes.

TABLE II.  
RATE OF FREE ASSOCIATIONS.

NO. OF WORDS	NO. OF SUBJECTS
20-29 .....	3
30-39 .....	3
40-49 .....	1
50-59 .....	6
60-69 .....	7
70-79 .....	11
80-89 .....	10
90-99 .....	6
100-126 .....	7

From the above table we obtain the following results:

Mode .....	70-79
Median .....	70-79

The exact median proves to be 75 words, which coincides with the minimum requirement for a normal adult. The lowest number of words said by any subject was 21, the highest number, 126. It is interesting, also, to note that 26.6% of the subjects fail to meet the Binet-Simon requirement for the twelve-year-old mentality.

The following table presents the individual record of each candidate.

TABLE III.  
RECORD OF SUBJECTS TESTED.

SUBJECT	AGE	SEX	EDUCATION	MENTAL AGE	MENTAL GRADE
A	M	35	80	College grad	Slightly subnormal*
B	M	29	96	High sch 2	Normal

160	F	23	88	Gram. sch. 8	Normal

#### CONCLUSIONS.

The following conclusions are drawn from the results presented in this paper:

1. A high percentage of defective and other-

wise mentally incompetent individuals is found among candidates seeking employment as attendants in state hospitals.

2. It is desirable that each candidate for employment should be submitted to a systematic psychological examination for estimating his general intelligence.

3. These results, though preliminary, empirically indicate that the federal and state civil services might well consider the plan of using reliable intelligence tests in their routine examinations.

### THE INTENSIVE GROUP OF SOCIAL SERVICE CASES.\*

By MARY C. JARRETT, BOSTON,

*Chief of Social Service, Psychopathic Hospital.*

WHEN the Social Service in this hospital was begun, two years ago, one year after the hospital opened, our first report was an orientation study of our function; next an estimate was attempted of the amount of social work there would be; and this was followed by further notes on the nature and size of our problem, with an estimate of the number of social workers who would be needed.† This year is evidently the time for a report on what we have done.

The nucleus of all our work is the intensive group of cases, and this report will go into detail in regard to them only.

By intensive, we mean those cases in which the Social Service Department has assumed responsibility for making an inquiry into the social condition of the patient and his family, and for taking steps to secure the greatest measure of social well-being possible for them.

\* Read at Third Annual Conference on the Medical and Social Work of the Psychopathic Hospital, June 18, 1915. Being Contributions of the Massachusetts Commission on Mental Diseases, Whole No. 161 (1916.19). The previous contribution, 160, 1916.18, was by C. S. Rossy, entitled "The Yerkes-Bridges Point Scale; as Applied to Candidates for Employment at the Psychopathic Hospital," BOSTON MEDICAL AND SURGICAL JOURNAL, Dec. 7, 1916.

In another group, known as Slight Service cases, the assistance given by the Social Service does not involve an inquiry into the patient's general situation beyond the apparent facts, nor responsibility beyond the particular service rendered. These two divisions of social ease work now seem to be generally recognized in most hospital social service departments.

In our two years' existence we have dealt with 440 cases in the intensive group, of which 68 are still under care. It happens that 440 is somewhat above the number of cases which, according to our estimate two years ago, two social workers would expect to deal with in two years. The hospital has only two social workers on the pay-roll of the State; but the help of students and other volunteers and several privately paid workers has made it possible to develop, in addition, several other lines of work—1238 cases have been dealt with in the slight service group; a Men's Club for discharged alcoholic patients has met once a month; a routine system of following up all out-patients who fail to report when due has been in operation a year and a half. Two pieces of work have been undertaken with the combined ideas of treatment and research,—first, a study of opportunities for psychopathic patients in industry; and second, a routine method of securing examination of the families of all syphilitic patients.†

The 440 intensive cases included 186 men, 185 women, and 69 minors. The following types of mental disorder and defect were represented:

Alcoholic .....	74
Backward .....	2
Delinquent .....	16
Drug habit .....	3
Epilepsy .....	16
Feeble-mindedness .....	35
Hysteria .....	10
Insanity .....	147
Neurasthenia .....	10
Not insane .....	47
Psychoneurosis .....	22
Psychopathic personality .....	7
Syphilis .....	18
Unclassified .....	14
All other diagnoses .....	18
Not made .....	1

The largest group were the insane, 36%+.

17% were alcoholic.

11%+ were psychoneurotic.

8% were feeble-minded.

3% were epileptic.

10%+ were diagnosed as not insane.

The remaining 14%, covering all other diagnoses, included syphilis, drug habit, delinquency, etc.

The different types of action taken may be classified as follows:

In 139 cases advice was given.

In 124 cases history needed by the doctors to make a diagnosis was obtained.

In 101 cases the patient was kept under supervision.

† Examination and Prophylaxis for Syphilitic Patients and Their Families: Methods of Investigation at the Psychopathic Hospital, by Helen M. Wright, Boston, Mass., 1915.

In 39 cases the patient was referred to another agency.

In 23 cases arrangements for the patient's discharge were made.

In 14 cases other members of the family were brought under care.§

By giving advice, we mean outlining a plan and, if necessary, assisting the patient or his family to follow it. An illustration of this class is the case of a backward child of eight in a family that contains four other defectives. The little girl is to be sent to the country for the summer. She is the original patient, but we now have the epileptic father as an out-patient. We keep general oversight of a feeble-minded son who is working, and we expect to persuade the father to make application to the School for the Feeble-Minded for a daughter of fourteen. A younger son is under observation in the out-patient department, and the over-burdened mother, by our advice, comes there also for reassurance in regard to her own mental condition.

An example of history necessary for the diagnosis is the case of a woman of thirty, daughter of a rag-picker, who had been supporting himself and her and his blind wife by begging, with the story of his daughter's broken-down health.

She was at first thought to be hysterical and was about to be returned to her father, but the history showed marked deterioration, and she was committed to a state hospital with the diagnosis of dementia precox.

Arrangements made for a patient's discharge may be illustrated by the case of an Irish servant girl, sent here for observation because she refused to eat or speak. She was pregnant and subnormal in intelligence. After investigation it was decided to secure her admission to a maternity home. The baby died and the girl is doing well in a position under the oversight of the Home.

An example of a case referred to another agency is a girl of fifteen, who had run away from home disguised as a boy. She was uncontrollable at home, and her parents were on the point of sending her to a reformatory. She was diagnosed as not insane and not defective. Under the care of the Children's Aid Society she has remained at home, worked regularly and attended night school, and is much improved.

To illustrate prophylaxis for other members of the family, the case may be given of a man with general paresis, whose wife and four children were brought in for examination. One child, a nervous, high-tempered boy, was put under treatment for syphilis.

The class of supervision cases have been left until last because they are the most intensive part of the group, and I want to speak of them in some detail. By supervision, we mean continuous oversight of a patient over a considerable period, from three or four months, to an indefinite time.

For example, a girl of sixteen, who was ad

§ See Appendix for illustrative cases.

mitted to the House two years ago twice in one month, with hysterical convulsions, is still under supervision. She has been educated in the control of herself, and has been helped financially so that she could study dressmaking. She has had several convulsions, but they have been much less severe and at longer intervals; and, in general, she is now in good health and good spirits.

The number of supervision cases dealt with was 101,—48 men, 41 women, and 12 children; 88 were at one time house-patients and 12 were out-patients only.

59 have improved.

42 have not improved.

18 were readmitted to the hospital and again discharged.

11 were committed to a state hospital.

3 went to reformatories.

1 went to an almshouse.

Of the 59 improved patients, 7 were re-admitted to the House and discharged after a short period. In 22 cases other members of the family needed assistance. For example, in the case of the hysterical girl just referred to, the father, who is alcoholic, has been made to report to the Out-Patient Department, and is somewhat improved. The purpose of our supervision may be classed as *after-care* in 37 cases, that is, no marked improvement in the patient's mental condition could not be expected; and as *prevention* in 64 cases, in which, under favorable environmental conditions, the patient might be expected to recover or to show marked improvement.

Some conclusions drawn from the study of 101 supervision cases are as follows:

1. The value of temporary residence in the Hospital as a therapeutic measure in some cases, shown in 7 of the 59 improved cases.

2. The possibility of a greater proportion of improvement than the 58% shown in this group through more careful selection of cases, since it is possible with a limited staff to care only for selected cases.

3. More attention to out-patients in the earlier stages of mental difficulties, with a view to prevention. It is probable that in our supervision work, there should be a smaller proportion of after-care than is indicated by the 37 cases in this group, compared with 64 cases for prevention.

4. A routine examination of every patient to determine his need of social care, to be held in view as an object when funds become available for a larger staff.

A beginning has been made in tabulating the social interests involved in psychopathic social service cases, following the division outlined by Roscoe Pound in his articles on "Interests of Personality," published in the *Harvard Law Review*, February and March, 1915, as an advance chapter of his projected book, "Sociological Jurisprudence." He distinguishes three

classes of rights or interests of the individual in relation to the environment,—individual, social and public. The study that we are making will be reported upon later in detail, and one conclusion only seems interesting to be mentioned now. Among the 440 cases studied, individual interests are involved to a greater extent than either of the other two classes, 647 times; social interests come next and are involved 544 times; while public interests are involved 409 times. The indication, therefore, is that the concern of psychopathic social service is primarily with the care of the individual; next, with the welfare of society, and finally, with the public good as represented in public institutions.

## APPENDIX.

### ILLUSTRATIVE CASES.

#### GROUP I. CASES IN WHICH THE PATIENT WAS KEPT UNDER SUPERVISION.

CASE 1. Bessie E., a girl of nineteen, was referred to the Social Service for supervision when discharged from this hospital about a year and a half ago. Her diagnosis was hysteria, with a question of dementia precox. She believed that her face was so ugly and "silly" that nobody could bear to look at her, so she would sit shrinking into a corner with her head turned against her shoulder, twitching and wriggling. She spoke only in a whisper, haltingly, and with a great effort. She was unfit for any ordinary occupation and very unhappy.

Her family consists of the mother, who has had two attacks of manic-depressive insanity, an excitable sister who works as a bookkeeper, a brother in school, and the mother's mother, 75 years old. The mother and sister were over-solicitous about Bessie and worried her by fussing over her. It was arranged that she should live with an aunt near the hospital and attend a cooking class and a gymnasium class at a neighborhood house. She also came to the hospital regularly for knitting lessons. In the beginning it took her a full minute or more to make one stitch. She improved and was happier. In the spring she was sent to a convalescent home in the country where her sister paid her board, and she gained noticeably in self-control while there. Arrangements were then made for her to board in a small working girls' home and work secured for her at a playground to play with the children, for which she was paid through a special donation. It is now planned to send her for two months to a girls' camp, under the management of a woman physician, money for her expenses having been raised by private subscription. She has shown marked improvement, and our hope is to continue to provide a thoroughly favorable environment until she has either recovered from her acute symptoms, or has shown a decided form of mental disease.

CASE 2. Harriet Q., aged 55, heard the big clock on her mantel talk to her in a vindictive manner. She had twice in two months become so violently enraged by it, that her husband had had to send her to the Psychopathic Hospital. When the time came for her second discharge, an effort was made to alter her home life, so that she would not be alone and unemployed as much as she had pre-

viously been. She took daily exercise out of doors, and through the coöperation of her relatives was visited, and kept busy. She reported regularly to the Out-Patient Department every two weeks and was no longer troubled by the clock. Her diagnosis was senile dementia.

**CASE 3.** James R.; was ready to be discharged, with a diagnosis of locomotor ataxia. He had been sent here because he had suicidal tendencies. He had been a teamster, and lived, with his wife, in the family of a married step-daughter, who has three children. We persuaded him to go to the State Infirmary because the doctors advised his having hospital care. After six weeks he went home because he was homesick. He spoke no English and could not make friends. The support of the patient was a problem, as the son-in-law was already over-burdened. The Overseers of the Poor were applied to, and gave \$2.00 a week. Arrangements were made with the district doctor to supervise the patient, and when, in two months, he had one of his attacks, the doctor sent him to the City Hospital, where he stayed two weeks. Recurring attacks of intense pain, with suicidal ideas, are to be expected. Attempts to secure some light employment for him resulted in a course in chair-caning at the Industrial School for Crippled Children. He did some work there until the school closed in the summer, and then a position was found for him in a factory, where, though the conditions were as favorable as possible, the strain was too much for him. He is very helpful in work about the house, and is now making a grind-stone with which he hopes to get work sharpening knives.

The weekly visit to the family has reassured them in regard to their fear of suicide, and has also been the occasion for some practical help and advice. The custom of keeping bantam hens in the house was eliminated, and later a family of kittens disappeared after comment from the visitor. A bed was supplied for two of the children who had been sleeping with the patient and his wife.

The Board of Health found the family over-crowded and told them to move. This trial was averted, as the agent of the Board was persuaded to remeasure the tenement, and discovered that it was his mistake. As the family were obliged to eke out their expenses by having two boarders in one of their rooms, they were more crowded than they should be, and we were hoping to do away with the boarders by securing more financial aid for the family, when the daughter decided to move to another tenement with her family. She needs an operation badly, which we hope to persuade her to have, after the baby recovers from an attack of dysentery, which she had this summer. She had been left weak and thin, and is still under the care of the district doctor and nurse. A vacation in the country was secured for her and two of the children during the hottest weather.

**CASE 4.** John O., a tailor, aged 39 (diagnosis, dementia precox, catatonic), had a wife and two children to support. His former employer, for whom he had worked thirteen years, was afraid of him when he returned from the hospital, and was quite satisfied with a younger man who was doing the patient's work for less money. Work had been scarce, and there seemed to be no place for a tailor who had once been called insane. Several visits

from the agent were made to the former employer before he could be convinced that the patient was now in condition to return to his work. He did, however, take him back and has allowed him a half day monthly to report at the Out-Patient Department of the Hospital.

**CASE 5.** Charles O., 17 years old, was before the court in a nearby town for setting fires. He had set three different fires within three months, each time playing the hero by discovering the blaze and helping to put it out. He was otherwise a good boy, mechanically inclined, but poor in school work. Before committing him to a reformatory, the court sent him to the Out-Patient Department for a psychological examination. In this he ranked above the normal, but showed a tendency to react too quickly, making conclusions before he had considered the whole situation. The court was advised to put him on probation and, as he had won general disfavor in his home town, to send him to Boston, to be under supervision of the hospital Social Service. He secured good lodgings where he would have the companionship of young men of his own age and temporary work, which would give him a chance to show what he could do. He gained the friendship of his employer, and appeared to be making good, when without warning of any mental disturbance, he set a fire in the building where he lived, and was again the hero of the occasion. As he had not improved in an environment thoroughly favorable, the court decided to treat him as a defective. After a period of observation in a state hospital, he was committed to a school for the feeble-minded.

**CASE 6.** John L., aged 39, a man of agreeable manners and appearance, educated in Ireland, where he nearly completed a medical course, is now employed by a large drug firm, who say he is extremely valuable to them.

He has been married six years and has two children. Two and a half years ago he came to the United States, and a year and a half later, brought his family. At intervals since his marriage he had had spells of drinking, when he was violent and abusive. During an attack, which lasted seven months, he required the care of male nurses.

He was brought into the hospital by the police because he had been abusive to his wife, threatened to choke her, and had thought people in adjoining apartments were talking about him. After two weeks he had recovered his mental powers. His employer, on the strength of assurances from the hospital, gave him back his position. Communication was established with his wife, who was seen at intervals at their home and at the hospital. She is an intelligent woman and realizes that there is danger of her husband's doing harm to her and the children when he is drinking. As he is without relatives or friends in this country, she has been especially grateful for the moral support of the social worker.

In June she came for advice, saying that her patient was acting strangely and had been drinking a little. She was told to have the police bring him into the hospital again at the first sign of violence. Two weeks later she sent a messenger to advise that the patient was drinking heavily and had threatened her. She was called in to see him in the police station, it was necessary. We then arranged for the police to bring him to the hospital. He cleared up an

ten days, again returned to his position, and has been in good condition since.

#### GROUP II. CASES IN WHICH ADVICE WAS GIVEN.

CASE 1. Arthur R., an Italian, 34, became violent at home, and through this hospital was committed to a state hospital, with the diagnosis of dementia precox. His wife and two children, aged  $5\frac{1}{2}$  and 4 years, were given lodgings with a relative who could afford the room, but had little means with which to provide food and clothing. The wife was restless, and worried constantly about her own dependence and her husband's illness. Work was, therefore, found for her in a candy factory, where she earned good wages as a chocolate dipper. The children were admitted to a Day Nursery in order to relieve the relatives of their noise and the quarreling between them and her own children. Subsequent visits found the wife happy in being able to contribute toward her own support, and the relations between the relative and the family were unstrained.

CASE 2. Benlah V., a quiet, refined woman, unmarried, was sent to the Psychopathic Hospital as a voluntary patient through a social agency, in the hope that a diagnosis might aid them in making future plans for her. It had seemed impossible to find her any work that she liked or would keep.

After a few days in the hospital, she decided not to remain, but was persuaded to stay as long as the doctors advised. After observation for nearly a month a temporary diagnosis of psychoneurosis was made, with the question of a possibility of early dementia precox. She returned to the social agency, tried several kinds of work, but finally gave up trying and went to live with an aunt. After a few weeks she refused to eat with the family, shut herself in her room alone, became suspicious of her aunt, and would not talk. The aunt, an intelligent woman, was instructed how to deal with the patient. She is keeping a diary of her conduct and changing moods, and in case she becomes unmanageable, will notify us, so that, if necessary, she can be brought back to the hospital.

CASE 3. Edward L., a feeble-minded boy of 15, was a great care to his mother, a woman of refinement, who had to support him and another child, a bright girl of ten years. Edward was masturbating badly, and had become so uncontrollable at times that he would beat his head against the wall and act more like an animal than a boy. A special effort was made to have him admitted to the already crowded school for the feeble-minded, and within three months the patient was having the care and training that he needed.

CASE 4. Anna L., a girl of 17, with a diagnosis of imbecility, came to the Out-Patient Department with her mother, who asked for help in getting her into the School for the Feeble-Minded, as she could not manage her. Over a year before, an application had been filed. We found that the girl could be received at Wrentham, and then the mother refused to sign the commitment paper. The father was sick in a hospital, the mother was too sick to be summoned into court, and the neighbors were supplying food and fuel. The Jewish Charities promised aid. After repeated efforts for two months,

during which the mother changed her mind many times, she was persuaded to sign the commitment paper, and the girl was sent to Wrentham.

#### GROUP III. CASES IN WHICH THE PATIENT WAS REFERRED TO ANOTHER SOCIAL AGENCY.

CASE 1. Martha O. The Brookline Court sent for observation a girl of fifteen, stating that she would stay away from home all day and often all night, and had recently gone to a hotel with a young man who promised to take her to New York. A month before she had attempted suicide. The patient was not insane nor intellectually defective. Her mother, a capable woman, employed in a position where she is well thought of, was at the end of her resources in managing the girl. By appointment, an agent from the Children's Aid Society came here to meet the mother. She has since had oversight of the girl, and reports that she has a position at clerical work in the same place with her mother, at \$8 a week; that she goes to gymnasium, and is doing very well.

CASE 2. Bessie N., had had an illegitimate child, and in the course of her efforts to find the deserting father, with the hope of making him marry her, her mind had become slightly unbalanced. In the hospital she recovered quickly.

With the help of her sister, who considered such a marriage inadvisable, and with advice from the Legal Aid Society, Bessie was persuaded to give up her search and accept the care of her child herself. It was found that she had an acute infection of gonorrhea. On her discharge from this hospital, she was referred to the proper department of a general hospital through their social service department, and she has been reporting regularly for treatment.

CASE 3. Julius R. was brought in by the police, because he was found trying to escape from imaginary people who were throwing things at him. The patient told a story that his wife was unfaithful to him and had driven him from their home in Brockton. He admitted that he was alcoholic, but claimed his wife was slack, and neglected both him and the children. The Society for the Prevention of Cruelty to Children in Brockton were asked to make inquiries about the patient, and to look into the condition of the children. The patient was transferred to Taunton State Hospital and later allowed to go home. The S. P. C. C. have the family under supervision, and have reported to us that the patient is apparently doing much better, and the wife, a woman of low mentality, after repeated efforts, has been made to clean up the house. The St. Vincent dePaul Society are paying the rent until the patient gets a steady job.

CASE 4. Timothy V. The patient, while in the hospital, said he was worried because his wife and two children had no means of support. A visitor was at once sent to see the wife, and though she was out, learned from the landlady that this was true. The Associated Charities were asked to help her, and the wife was seen, when she came in to visit her husband, and was put in communication with their office. She was also directed to take one of the children to the Children's Hospital. The patient was discharged to the Out-Patient Department with a question of cerebrospinal syphilis.

He was later committed directly to the Boston State Hospital, and the Associated Charities continued to assist the family.

GROUP IV. CASES IN WHICH PROPHYLACTIC MEASURES WERE TAKEN FOR OTHER MEMBERS OF THE PATIENT'S FAMILY.

CASE 1. Lester A., a feeble-minded boy; should have been sent to a school for special training, but as there was no vacancy, it was necessary to supervise him in his home. A few visits brought out the fact that his mother was suffering from violent headaches and "rheumatism." After an examination in the Out-Patient Department, she was advised to take hygienic baths, and gradually improved. It was also learned that her husband, a painter, was supposed to have been so affected by a fall on his head some ten years before, that his friends had not considered him normal since. He had been getting gradually worse, and had been suffering from "spells" of some kind. After much persuasion, he also came to the Out-Patient Department, and his examination showed a low grade of mentality and signs of lead poisoning. He was sent to another hospital for treatment. The mother's headaches have improved. The father was operated upon for appendicitis, and during his convalescence the family was aided financially through two charitable agencies. On recovery, he obtained a position in the Park Department. The original patient, Lester, is still at home and doing fairly well in a class for backward children.

CASE 2. Lester K., 12 years old, two months before his admission had become blind after a convulsion. He appeared frightened, his speech was defective, and he had lost flesh rapidly. The Wassermann reaction for syphilis was found to be positive, and a diagnosis was made of juvenile paresis. His parents took him home, although they were advised to have him committed to a state hospital for the insane. The mother and two brothers were examined in the Out-Patient Department and given the blood test for syphilis. The younger boy of six showed a negative reaction. In the case of the older boy, fourteen years, the test was unsatisfactory and he is to return for a second test and also for a psychological examination, as he is reported to be "dull." The mother's examination has not yet been completed.

The father was also examined and found to have a positive Wassermann reaction. Inquiry from a physician showed that he had previously been treated for syphilis. He was advised to have further treatment at once.

The father's physical condition prevented his earning enough to support the family, and the mother was obliged to go out to work. The care of Lester was too great a burden, but the parents were unwilling to send him to an institution. As the home of the family is in another city, the case was referred to the local Associated Charities. They report that the father is under the care of a physician, and the mother is partly persuaded to allow Lester to be sent to a state hospital.

CASE 3. Howard R., a married man of 28, with cerebrospinal syphilis, is receiving salvarsan treatment. His wife and two children were given the Wassermann test for syphilis in the Out-Patient Department. The children showed a negative re-

action. The reaction of the wife was positive and she was persuaded to put herself under treatment at a general dispensary. The patient's treatment quickly exhausted his small savings, and the Social Service furnished the money for salvarsan until his mother could be persuaded to pay for it. As the patient's illness left the family without support, they were referred to the Overseers of the Poor, and received temporary aid until they were transferred to the care of the Mothers' Aid Department of the State Board of Charity.

GROUP V. CASES IN WHICH HISTORY REQUIRED FOR DIAGNOSIS WAS OBTAINED.

CASE 1. James R. told a story of abuse and unfaithfulness on the part of his wife, claiming that she was a "devil at home" and wanted to get rid of him. When she had him arrested for non-support, he became so excited because he said everybody believed her instead of him, that he made a scene in court, which resulted in his being sent here for observation. He had been once before in an insane hospital, where no definite psychosis was found. At that time he had attacked his wife when drunk. He gave no evidence of a psychosis when here, and was discharged. He went on a cruise, and on his return was immediately sent in by the police. This time an investigation was made by the Social Service. Careful inquiries established the fact that the wife was a good, hard-working young woman, struggling bravely, with the help of her own family, to bring up her children nicely; was in terror of her husband, and had suffered ill-treatment from him. Indications of mental disorder were found in the history, and the patient was committed to an insane hospital. A copy of the social service history was sent with him.

CASE 2. James G. fractured his skull by falling from a scaffolding at his work, and a year later was sent to the Psychopathic Hospital for observation. It was difficult to tell to what extent his dizziness, lack of self-control and slight paralysis of the right arm were induced by the nine dollars a week which he was collecting under the Employer's Liability Act. All data at first pointed toward a diagnosis of psychopathic personality. A careful inquiry later into his character, his general health, and the events preceding and following the accident made it possible to make the diagnosis of traumatic psychosis.

GROUP VI. CASES IN WHICH ARRANGEMENTS WERE MADE IN ORDER THAT THE PATIENT MIGHT BE DISCHARGED.

CASE 1. Caroline O., an old woman, was reported to the overseers of the poor by a neighbor, who found her living alone in a tenement in destitution. The agent thought her manner strangely confused, and called a physician, who sent her here for observation. Inquiries showed that she had deserted her husband when her children were young, and had since lived alone, drinking steadily and consorting with disreputable people. She had resisted all the efforts of her daughter to induce her to live respectably.

After it was determined that she was not suffering from a psychosis, the question was, where was she to go. She was physically weak, and confused and rambling in mind, requiring the doctors' said hospital care. Her daughter was sent for, at home

with her husband. They had given up the filthy tenement in which the patient had lived, so that she might not return to it. They were not able to afford the expense of a nurse for the patient, and she was too unmanageable to be taken into their home, so that they were advised to send her to the State Infirmary. Her admission was arranged for, and, after a stubborn resistance, the patient was persuaded to go.

CASE 2. JAMES B., 65 years old, came into the hospital in a disoriented condition. A month previous he had been knocked unconscious by an engine while at work. He was a moderate drinker, but had been a steady worker for the railroad twenty-four years. His mind cleared slowly, and by the middle of the second month he was ready to be discharged. Inquiry showed that none of his five children were in a position to give him a home, and all agreed that he ought not to return to his second wife, a chronic alcoholic. Arrangements were, therefore, made to send him to his brother in Nova Scotia. There he spent four months on a farm and gained strength, so that when he came back in the fall, he returned to his work with the railroad. He lives with another brother in the city and reports to the Out-Patient Department.

CASE 3. Harriet L., 19 years old, was brought to the Psychopathic Hospital for observation, at the suggestion of the family physician. She had been in the habit of stealing from members of her family and friends ever since she was a small child, and recently had had immoral relations with several men. Unless she could support herself, her brother was not able to have her live in his family longer; but because of her habit of stealing she could not be recommended to employers.

She was found to be a high grade moron, and institutional care was recommended. An application was sent to a school for the feeble-minded, and the patient's name was put on an already long waiting list. Later, through our representations, she was listed among the "urgent" cases. Meanwhile, it was necessary to keep her under custodial restraint somewhere, and a small private institution finally agreed to take her temporarily, making an exception to their rule not to receive mental defectives.

At the end of three months, however, the matron said that she could not keep the girl any longer. She had plotted to escape with another girl, and her influence in the Home was bad. As no other place could be found, she was sent to the State Infirmary until she could be admitted to the School for the Feeble-Minded. There she took such a violent dislike to the women with whom she was associated that she was given night work, so that she would not have to be with them. At the end of three months she was admitted to the school, where she is said to be mingling well with the older girls, and seems to be happy.

CASE 4. Walter A., an unmarried man, was sent for observation, because the woman with whom he boarded claimed that he had violent fits of temper, when he would destroy clothing and furniture, and because, as he also lacked all ambition and initiative, he had been suspected of mental defect.

Inquiries from neighbors in the country town

where the patient had boarded, showed that he was not considered harmful by neighbors who saw him daily. The landlady was reported to be a woman with whom "an angel from heaven" could not live peacefully. On the wards his conduct was excellent. The nurse in charge reported that he was one of the most willing and obedient patients she had ever had. The diagnosis of dementia precox simplex was made, and the patient was not considered committable.

As the patient's mother had left him some property, in charge of a guardian, board could be paid for him at \$5.00 a week. A place in the country was found in the family of a widow and her daughter, where he could help with the chores, and perhaps obtain some work in the neighborhood. We have received several letters from the patient, telling how much he likes his new home. The family are well satisfied with him and are delighted that they have a permanent boarder.

### AN EXPEDIENT FOR THE RADICAL CURE OF SOME RETROVERSIONS.

BY EDWARD REYNOLDS, M.D., BOSTON.

THE choice of treatment for most retroversions of the uterus has long been settled in favor of operation, rather than the pessary. The majority of the retrodeviations are dependent either on inflammatory complications which can be relieved only by operation, or are the result of minor abnormalities in the supporting mechanism which predispose to retrodisplacement and which will predispose to its recurrence unless they are corrected by operation. The pessary is, as a rule, a palliative rather than a cure, and should be so regarded and described.

Occasionally a recently retroverted uterus, occurring as the result of a fall or during puerperal relaxation, will remain permanently forward after a few months' use of pessaries and their gradual reduction in size during the process of dispensing with them; but these cases are few and belong to a class by themselves. For the rest, the use of pessaries may be judiciously restricted to those cases of uncomplicated retrodisplacements in which it is desirable to postpone an operation for some reason in the circumstances of the patient; and prominent among these are the not infrequent cases of women in the child-bearing period who desire to postpone an operation until after the family is completed. Such women not infrequently endure the annoyance of a pessary for many years except when pregnant, having it reinserted so soon as they are out and about, a few months after childbirth, and wearing it until well advanced in the next pregnancy.

A considerable experience has convinced me that these women form the only class, outside of the very few acute cases mentioned above, in

which retroversion is curable by means of a pessary; and my experience further leads me to believe that most such cases (of uncomplicated retroversion) are so curable. (I am referring only to cases in which the uterus is freely replaceable and in which a properly fitted pessary is worn with comfort.)

In these cases the vagina is usually capacious, the uterus somewhat heavy, and all the tissues relaxed. Labor is usually rapid and the perineal floor either intact or sufficiently good to furnish thorough support for the pessary. Cases in which the pelvic floor is extensively lacerated do not come within the class which I am discussing, and, indeed, are seldom comfortable with a pessary.

The treatment ordinarily adopted in the management of these retroversions is that the pessary is removed before the middle of pregnancy, and is not replaced until the woman again complains of backache and bearing-down sensations, which is usually when the child is from six weeks to three months old. The uterus is then replaced and the pessary reinserted. If such a case is closely observed it will be found that the uterus returns to its retrodisplacement at approximately the end of the third week of the puerperium; it then usually remains heavy and subinvolved until it is replaced and a pessary inserted.

The structures which support the uterus are all muscular—they are all, from a physiological standpoint, uterine adnexae, *i.e.*, they are as much a part of the uterus as an ell is a part of a house. They evolve (increase in size and lose rigidity) with the uterus during pregnancy; they involute (shorten and resume firmness) with the uterus during the puerperium.

These considerations furnish the all-important point. If these structures are allowed to involute during the puerperium, with the uterus held by its own weight and by the intra-abdominal pressures in a retroverted or retroflexed position, they of necessity possess at the end of their involution the degree of length and relaxation which results in an absence of tension, *i.e.*, in a comfortable adjustment of tensions, with the uterus in this abnormal position. They are no longer capable of sustaining the uterus in its proper position. They remain relaxed and subinvolved with the uterus until the organ is replaced and raised by a pessary. A universal experience has shown that they do not then undergo sufficient resumption of activity to enable them to perform their supporting functions effectively.

All that is necessary to secure effective puerperal involution of the supporting structures, and a cure of the retroversion, is so to arrange the puerperium that the supporting structures undergo involution, and complete involution, while the uterus is held in an extreme forward position. Under these circumstances the supporting structures will almost invariably shorten

and resume firmness to a degree which will hold the uterus permanently in a normal position.

At a period in the puerperium at which the uterus is too large to be capable of retroverting, *i.e.*, between the tenth and fifteenth day of the puerperium, the uterus should be thrown into strong anteversion bimanually, and a carefully fitted, hard rubber pessary should be made to hold it there. Such a pessary will usually be larger than the stock sizes and must often be specially procured. Very hot vaginal douches should then be administered twice daily. From two to four quarts should be used, and the injection should last from fifteen to twenty minutes. It should be given with a fountain syringe and under a fall of not more than twelve to fifteen inches in order to avoid forcing fluid through the open os.

In this position of the uterus and under the influence of the hot douches involution is usually very rapid. In most cases it will be found that within a week the original pessary will have become too large and too highly curved for the contracting vagina. A second and smaller, but equally well fitting, pessary should then be adjusted, and the douches continued. This will usually need to be replaced by one of lesser size in from ten days to a fortnight, and after a few weeks this must again be reduced. The hot douches should be continued until the uterus is but little above the normal size and firmness, but should then be intermitted, as too long a continuance of the douches sometimes results in hyperinvolution, which might cause subsequent dysmenorrhea.

Uncomplicated retroversion is not a serious lesion, but it is not so innocuous as some general surgeons would have us believe. Women with retroverted uteri are always more liable to inflammatory attacks from slight exposures than those with normally placed organs. The majority of them have backaches and uncomfortable catamenia; most of them, sooner or later, seek relief. Unnecessary operating is objectionable. The prolonged use of a pessary is dangerous if the instrument is not frequently cleaned and repolished more dangerous than most practitioners realize. If it is properly cared for it is in many minor ways more objectionable than any one but the patients realize. The prolonged use of a pessary is a worse thing than an operation in the majority of cases. It is tolerable only when an operation is, for some reason, inadvisable.

The relief of the class of multiparae which I have attempted to define by the simple means described has been with me so nearly uniformly successful that I am surprised that the method has not attracted general attention. As I have never seen it published, I am led to put it on record as worthy of wider use, but with the caution that the use of large pessaries during the early part of the puerperium demand special care and probably a reasonable degree of special

skill, to say nothing of asepsis. I have never seen harm result, but am so far sure that carelessness might easily result in trauma, that I would not recommend the procedure, valuable as I believe it to be, to practitioners who are not in the habit of using pessaries, nor familiar with the process of fitting them to the individual case.

## ETHER ANESTHESIA.

By H. H. AMSDEN, M.D., CONCORD, N. H.

*Visiting Physician, Margaret Pillsbury General Hospital.*

WHILE intraspinal, intravenous, rectal and gas-oxygen anesthesia are indicated in selected cases and in skilled hands, yet ether by inhalation remains the safest, simplest, and most economical anesthetic for general surgical purposes. Gas-oxygen is, doubtless, the ideal general anesthetic, if administered by an expert, but otherwise it is not as safe as ether, and the cost prohibits its use in all but a small number of cases.

The researches of Boothby, Henderson, Bryant, Hewitt and others have apparently established two facts regarding the physiology of anesthesia: (1) A definite ether percentage is necessary, below which it is impossible to maintain anesthesia, and above which there is danger of overdosage. Boothby has experimentally established these limits as from 15% to 30%. (2) A certain amount of re-breathing is desirable, as loss of  $\text{CO}_2$  is thereby prevented; this is claimed to be an element in the causation of shock.

The best method is the one which permits the giving of a concentrated ether vapor, in such manner as to prevent excessive  $\text{CO}_2$  loss, or, in other words, a closed rather than an open ether; yet the open drop method is, doubtless, used more extensively than any other today, in this country at least. An ideal ether would call for the following points: (1) Safety; this factor largely depends upon the anesthetist, more than upon the method or apparatus used. It is necessary to watch the patient's color, pupillary reflex, depth and rate of respiration, and pulse, and unless the anesthetist is fully aware all the time of the patient's condition in these respects, the factor of safety is not provided for. (2) Simplicity; while ether apparatus doubtless facilitates its administration, it is not available for general use, in private practice, or in small hospitals. (3) Economy; other things being equal, the method which uses the least ether is most desirable. (4) Comfort; absence of choking, coughing, initial vomiting, or struggling, minimum secretion of mucus, and minimum amount of post-anesthetic nausea.

A preliminary hypodermic of morphine and atropine should be given to adults, and atropine by mouth to children. The Allis or similar open

cone is used for preliminary anesthesia. The cone is placed over the patient's face, and he is allowed to breathe for a minute or two before the anesthetic is started. A few drops of alcohol, menthol solution, or some mild perfume is then dropped on the cone, followed by a few drops of ether. The gradual administration of ether by the drop method is essential for a smooth initial anesthesia; under no circumstances should enough be given to cause coughing. As the stage of excitement is reached and the respirations become deeper and more rapid, it is necessary to give a higher percentage, and this can be done by putting on more ether and by covering the cone with the hand or with a folded towel. It is essential to obtain full surgical anesthesia before discarding the cone, as the patient cannot easily be carried by the stage of excitement and deep breathing, unless the cone used permits the giving of a closed ether. It is very difficult to obtain a sufficient ether percentage under these circumstances with any mask or device which does not permit complete exclusion of air if desired, as only in this way can the necessary percentage be obtained. After full surgical anesthesia is secured, the cone is replaced by a sponge consisting of six or eight layers of coarse mesh gauze laid directly over the nose, which has previously been smeared with vaseline. The chin is held up with one hand, thus closing the mouth, so that respiration is wholly nasal. The ether is dropped on the sponge directly over the nostrils. The practical results of this method are a smooth ether, with minimum secretion of mucus; the patient's color is pink, and anesthetic equilibrium, so to speak, can be maintained, so that, while the patient can be held always under surgical anesthesia, yet the anesthesia is so light that there is no danger of overdosage.

This primitive method of etherization seemingly contradicts the statement that a closed, rather than an open, ether is desirable. The advantages of the closed method are high ether percentage, and re-breathing. When we study more closely what really happens with the method described, it is evident that it is possible to secure a high percentage in this way; the ether is dropped directly over the nostrils and inspired immediately, and if the dropping is timed to coincide with inspiration, very little ether is lost by evaporation. As regards re-breathing, it is apparent that if respiration be wholly nasal and a moist sponge be laid directly over the nose, expiration is sufficiently obstructed to secure a certain amount of re-breathing.

The most important detail in this method, however, is its use of the nose as the sole route of inspiration. The physiology of the nasal mucous membrane has apparently not been sufficiently considered, in its relation to anesthesia, namely, its function of warming and moistening inspired air. If nasal respiration is physiologically proper, then it would follow that the

nasal route is the proper one for anesthesia. It is claimed that warm ether vapor is preferable, because it is less irritating to mucous membranes, and because the loss of body heat which is expended in warming the ether vapor is detrimental. Leaving out of the question the possibility of warming ether vapor, which is denied by some authorities, it may be said that the heat loss entailed is negligible, and that if the nasal route is adopted and the functions of the nasal mucous membrane utilized, warming the vapor is totally unnecessary. Another noticeable feature with this method is the small amount of mucus secreted. Ether vapor is irritating to mucous membranes, and if inspired directly through the mouth, a copious secretion of mucus occurs, whose presence in mouth and throat is very annoying and may be dangerous. It is probable that the presence of a large amount of ether-laden mucus in the stomach is partly responsible for post-anesthetic nausea and vomiting. If the nasal route is adopted, the secretion of mucus is much diminished.

The adoption of this method presupposes free nasal passages, and the presence of polypi or adenoids may render its use impossible. In some cases in which the nose is clear it will be found that the alae nasi collapse on inspiration, preventing free ingress of air. Some device to hold the nose open may be necessary, and a simple one is three medium size safety pins, two of which are inserted in the nostrils, while the third, lying across the columella, holds the others in place.

The results of this method as used in some 300 cases, show that it conforms very closely to the standard set for an ideal ether, namely, safety, simplicity, economy and comfort.

### Book Reviews.

*The International Medical Annual. A Year Book of Treatment and Practitioner's Index.* New York: William Wood & Company. 1915.

The English edition of this standard British Year Book for 1915 was reviewed in the issue of the JOURNAL for October 28 of that year (Vol. CLXXIII, p. 672). This American edition for 1916, being the thirty-fourth annual issue, is this year more punctually published. It is notable for the large amount of space devoted to naval and military surgery, to which a special section is given at the end of the dictionary of new treatment. Special injuries to organs and nerves are considered under their proper headings in the body of the work. Other branches of medical study are not neglected. The most notable changes in the list of contributors this

year are the absence of the late Sir Charles Bent Ball, who for eight years was a collaborator in the production of the Annual, and the addition of the names of Dr. Lewis A. Conner and Dr. J. Ramsey Hunt of New York, who have assumed charge respectively of the sections on pulmonary diseases and diseases of the nervous system. The volume is illustrated with fifty-three full-page plates and sixty-four text cuts, a considerable reduction from the number in the previous volume. The number of reading pages, however, remains the same. The volume maintains its standard of value and has new and unusual features of interest.

*The Practical Medicine Series.* Comprising ten volumes on the year's progress in Medicine and Surgery. Under the general editorial charge of CHARLES L. MIX, A.M., M.D., Professor of Physical Diagnosis in the Northwestern University Medical School. Volume V. *Pediatrics*. Edited by ISAAC A. ABR, M.D., Professor of Pediatrics, Northwestern University Medical School, Attending Physician Michael Reese Hospital. With the collaboration of A. LEVINSON, M.D., *Orthopedic Surgery*. Edited by JOHN RIDLON, A.M., M.D., Professor of Orthopedic Surgery, Northwestern University Medical School. With the collaboration of CHARLES A. PARKER, M.D. Series 1916. Chicago: The Year Book Publishers. pp. 232, 1916.

This little book, which is one of a series of ten, published annually and devoted to the progress of the year in medicine and surgery, is made up of abstracts from periodical literature with editorial comments. The articles chosen for review are on the whole well selected and fairly representative of the thought of the year in pediatrics and orthopedic surgery. The editorial comments in the section on pediatrics are good. Those in the section on orthopedic surgery seem to the reviewer to show considerable personal bias and to be more caustic than necessary.

*Gynecology.* By WILLIAM P. GRAVES, M.D., F.A.C.S., Professor of Gynecology at Harvard Medical School. Octavo volume of 770 pages with 424 original illustrations, 66 of them in colors. Philadelphia and London: W. B. Saunders Company. 1916.

This latest work on Gynecology is based on the wide experience of the author in the pathological laboratory, clinic, operating room and class room. It is designed both as a textbook and as a general reference book of gynecology.

in one volume. Thus, from the start it was composed under a serious handicap which the division into three parts cannot overcome.

The first part deals with the physiology of the pelvic organs and with the relation of diseased pelvic organs to other parts of the body. It is the most valuable section of the book and Graves has rendered a distinct service to American students in emphasizing the point of view and stating the facts so familiar to German investigators. Space did not permit more than this too brief yet suggestive treatment of the subject, and the literature, to which especial reference is here made, should be far better known.

The second section is "designed primarily for the undergraduate student who is taking his initial course in gynecology." Whether the needs of the third year students in our best medical schools, for whom presumably the book is written, are best met by so "compact" a presentation is at least questionable. Many high educational authorities advocate more detailed and comprehensive studies for university men.

"The third part is devoted exclusively to the technic of gynecologic surgery" and also shows the defect of too great "compactness."

The style is direct, clear and pleasing, so that one reads easily page after page without being disturbed by the grammatical and rhetorical infelicities so common in current American medical literature. The book is thoroughly up to date and does not contain the vast amount of discarded material one finds in even recent editions of some older works. Perhaps too much has been rejected, but the book is a refreshing departure in this respect, and actually contains considerable information not easily accessible elsewhere. More detailed references to the literature, however, would give great enhancement of value. The illustrations are, in general, excellent, many of them by the author himself. But the propriety of so many representations of microscopic sections in a work of this character is doubtful. While some are characteristic and helpful, others might be dispensed with easily.

*Oral Abscesses.* By KURT H. THOMA, D.M.D.  
Boston: Ritter and Company, 1916.

The recognition of the importance of infections associated with the teeth as modes of entry for systemic diseases, and as reservoirs of infection from which repeated metastatic distribution may occur throughout the body, is relatively recent, and has resulted in the rapid development of a new and large technical field in dentistry. At the same time it has resulted in a much closer coordination between dentistry and medicine and should do much to break down the unnatural demarcation hitherto existing between the two. Not only is knowledge of general medical diseases essential to the den-

tist, but equally essential to the physician is an understanding of the phenomena of dental infection and its relation to the somatic diseases which it is his part to treat.

The present volume, by an author hitherto well known for his work in oral anesthesia, aims to supply a book which shall furnish, both to the dentist and to the general practitioner, the necessary information for their mutual instruction in the nature and progress of dental infections, their relation to the general health and their treatment. It is divided into a series of twelve chapters dealing systematically with successive aspects of the subject and abundantly illustrated with 293 figures presented on seventy-nine full-page plates, of which a number are colored. There is an excellent terminal alphabetic bibliography of about 100 titles on the subject. The book is well and clearly printed, and is highly commended to both dentists and physicians.

*Practical Bacteriology, Blood Work and Animal Parasitology.* By E. R. STILL, A.B., PH.G., M.D. Fourth Edition Revised and Enlarged. Philadelphia: P. Blakiston's Son and Company, 1916.

This fourth edition of a well-known laboratory manual, originally based on the author's experience as a member of the United States Naval Examining Board, aims to incorporate a large amount of new material without materially increasing the size of the book. This has been accomplished by a greater use of paragraphs on minor subjects in small type. A further economy of space is effected by printing tables and other material on the inside of the covers and on the fly leaves. In spite of all these economies, the volume is increased nearly one hundred pages over the preceding edition. Every chapter in the book has been carefully revised and in many instances, rewritten. A new chapter has been added on diseases of doubtful or recently determined etiology, such as beri-beri, pellagra, oryza fever, veruga Peruviana, Rocky Mountain spotted fever and sprue. In the appendix a new section has been added on clinical blood examination and a section on anatomic and physiologic norms. Many new tests are, for the first time, incorporated in this edition, such as the Schick and colloidal gold tests. The volume is conveniently divided into four parts, dealing respectively with bacteriology, study of the blood, animal parasitology and the clinical examination of the various body fluids and organs. An appendix contains bacteriological keys, zoölogic tables and explanatory clinical notes. The book is illustrated with four plates and 115 other cuts, containing 505 figures. It should maintain its value as a comprehensive laboratory text-book and manual.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned to writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager*.

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

## THE DOTEN BILL.

On page 840 of this issue of the JOURNAL appears the full text of the Doten Bill, House No. 1015. The importance of this bill is so great that everyone should become familiar with its major points. The measure, if it becomes a law, and if it has the effect in this country which it has had in Great Britain and in Germany, should increase materially the health of the industrial class through providing earlier medical care and through the reforms in industrial sanitation which will be brought about.

The effect of health insurance upon the practice of medicine is less easy to predict. That it will inaugurate changes of great significance seems highly probable and for that reason, if for no other, every physician in this state should read carefully the full text of the bill. Briefly stated, the system of insurance as outlined by the bill is as follows:

The state is divided into districts in which local health organizations, or organizations comprised of workers in certain trades, are formed. In one of these associations every person employed for compensation not greater than one hundred dollars a month must be enrolled. Certain persons, such as federal employees and those already provided for, are exempted. Certain other workers who are not employed at a regular wage, such as those working at home, may enroll if they wish.

These local associations or "carriers" are supported by contributions from employees, employers and the state. Of the two former, each pays two-fifths; the state, one-fifth. In the case of employees earning nine dollars a week, or less, the proportion paid by the employee becomes less as his wage diminishes. In the case of those earning only five dollars a week the employer pays the entire four-fifths.

In return for this expenditure, the employee gets medical, surgical and nursing care, treatment in a hospital if needed, sanatorium treatment for tuberculosis and a cash benefit for the support of his family while he is unable to work. The cash benefit is given for as long as 26 weeks and amounts to two-thirds of the man's wages if he is at home, or one-third if he is in a hospital. Women get obstetrical care, and perhaps may receive cash benefits during confinement.

The administration of the whole matter is in the hands of three commissioners who are full time, salaried officials. To advise with these there is a council, called the Social Insurance Council, composed of twelve members, six representatives of employers and six of employees. This council meets at least four times a year. Each local health or local trade health association is governed by a committee of from twenty to two hundred members and by a board of directors of eight to eighteen members elected by the committee. Employers and employees are equally represented upon these boards.

As to the manner in which medical service is to be rendered, the bill is very nearly silent.

Part II, Section 3, states that all necessary medical, surgical and nursing attendance and treatment shall be furnished by the carrier. "In case the carrier is unable to furnish the benefit provided for in this section, it must pay the cost of such service actually rendered by competent persons at a rate approved by the commission."

Part II, Section 4, states that "the carriers, subject to the approval of the commission, shall make organized provision for medical, surgical and nursing aid by duly qualified physicians, surgeons and nurses, or through institutions or associations of physicians, surgeons and nurses as required by this act."

Part II, Section 6, "Hospital or sanatorium treatment and maintenance may be furnished instead of all other benefits. . . This benefit may be provided in those hospitals with which the associations and societies have made satisfactory financial arrangements which have met the approval of the commission or in hospitals erected and maintained by the associations and societies with the approval of the commission."

The board of directors of the local associations shall have the power to "make contracts with physicians, hospitals, pharmacists and any other persons necessary for the business of the association." It seems, therefore, that the relation of the association to the physician is left to the discretion of the board of directors of each association, subject to the approval of the Social Insurance Commission. Probably these relations will vary in different localities. In smaller communities all the local practitioners may serve on the panel of the association, whereas in larger communities, particularly those given over to well-organized industries, the insurance associations may have their own staff of physicians and even their own hospitals.

The question of choice of physicians by the sick is not mentioned in the bill. Doubtless it was felt by the authors of the bill that the powers given to representatives of employees would be sufficient to insure conditions satisfactory to the insured. The situation thereby differs from that now obtaining in regard to the Workingmen's Compensation Act, in the machinery of which employees have only the very remotest authority. The effect of the Doten Bill upon the medical profession is impossible to foresee. In England, in spite of the fact that the insurance system embodies some unsatisfactory features which the Doten Bill will avoid, the sum set aside annually for the remuneration of physicians is nearly twice the average physician's income before the insurance went into force.

From the point of view of the practitioner, health insurance, so far as it tends to cut down the number of patients now receiving charity treatment, is excellent and a just measure. The

profession, however, must be united in insisting upon fair remuneration for services rendered. The doctor will no longer be independent, but will be responsible to the association which employs him, and this responsibility should check the tendency, inherent in all contract practice, to perform one's work in a machine-like and superficial manner. He can look to the association for payment for his services, and in these ways the financial side of medical practice should be on a more business-like basis.

Once more we beg all physicians to consider this bill most carefully and, with unprejudiced mind, answer these two questions: Will health insurance improve the public health? Will it improve the condition of those who have invested so much time and money in order to acquire the equipment necessary for the practice of medicine?

#### RETROVERSION AND PTOSIS.

IN another column of this issue of the JOURNAL we publish a valuable article by Dr. Edward Reynolds of Boston, pointing out the possibility of successful treatment and radical cure of certain cases of uterine retroversion without surgical operation. With this article we wish to take a single exception, and that is to its first sentence. Though it is doubtless true that a majority of surgeons treat the majority of retroversions by surgical operation, rather than with the pessary, we believe it is far from being settled that this preference is judicious, sound and necessary.

As a matter of fact, the majority of uterine retroversions are really but one of the many manifestations of visceral ptosis. The failure of many men successfully to correct retroversion by the use of the pessary, and the consequent disrepute into which that valuable appliance has fallen, are due largely to the non-recognition of this fact and the consequent failure to employ the other necessary mechanical means for the correction of the associated ptosis. It is manifestly often difficult and frequently impossible with a pessary to sustain permanently the retroverted uterus in the face of superincumbent enteroptosis. Not until the prolapsed intestines are raised and held by a properly applied corset, can the uterus, whose retroversion, in the absence of adhesions, is usually maintained solely by their weight, be

restored and held in its own normal position. Moreover, not infrequently the mere correction of enteroptosis by proper corseting is alone sufficient to make the retroverted uterus rise of its own accord into normal position, without further manipulation or apparatus. The pessary is not to be regarded, therefore, as a permanent appliance, but as a temporary splint to be used merely until the retraction of stretched ligaments insures the permanent maintenance of normal position. Without the simultaneous correction of intestinal ptosis, the use of the pessary either is unavailing or must be permanently maintained; with the correction of such ptosis, the pessary can usually be dispensed with permanently within a few months. The employment of the *donche*, as Dr. Reynolds points out, is a valuable adjuvant to this method of treatment since it assists the depletion of engorged pelvic tissues and expedites the involution of uterus and ligaments.

It is doubtless true that in nulliparae the correction of retroversion by this method is much more difficult than in parous women. Oftentimes a preliminary period of treatment with douches and the correction of abdominal ptosis by a corset should be followed in these cases by manual replacement of the uterus and insertion of a suitable pessary under ether, following which the pessary may generally be removed at the end of a few months without the recurrence of the retroversion, provided the use of the corset and douche has been faithfully continued. With patience and perseverance nearly as large a percentage of results may be obtained in these cases as in those of parous women. In the latter class of cases, the use of douches and suitable corsets should be begun at the end of the second week of the puerperium, provided retroversion then exists and there is no septic or other complication. It is our firm belief that by the intelligent and correct employment of this method, which rests, as we have said, upon recognition of the fact that the majority of uterine retroversions are really a manifestation of visceral ptosis, a majority of such cases may be radically and mechanically cured, leaving the employment of surgical operative procedures for the relatively limited minority of cases in which the uterine retroversion is caused, complicated or maintained by pelvic inflammatory process, neoplasm, or adhesions.

## STANDARDIZATION OF FIRST-AID METHODS.

AMONG the various activities and endeavors inspired by the theory of national preparedness, that of the spreading of first-aid knowledge among laymen deserves high commendation. Dr. Joseph C. Bloodgood of Baltimore first brought forward the idea of a standardization of first-aid methods, reducing such procedures to simple terms, teaching them to laymen and thereby saving, by prompt action, lives and health otherwise lost and endangered by inability on the part of laymen to meet emergencies. Through his efforts the American First-Aid Conference was held in Washington on August 24, 1915. For several sessions the assembled doctors debated the problem of preventive surgery from the layman's point of view and planned an organization which was effected before they adjourned. This first organization, under the presidency of Dr. William C. Gorgas, surgeon-general of the army, had no money and its labors were all voluntary. It was suggested that President Wilson appoint a board who might be empowered to carry on the work of such an organization. This the President did, calling the new board the Board on Standardization of First-Aid Methods and naming Dr. Richard H. Harte of Philadelphia chairman. The vice-chairman is Colonel Louis LaGarde of the Marine Corps, and Dr. W. C. Rucker, assistant surgeon-general of the United States Public Health Service is secretary. The other members consist of Dr. J. P. Kaster, chief surgeon of the Atchison, Topeka and Santa Fe Railroad; Dr. Samuel C. Plummer, an authority on fractures, and Dr. Shelton Horsley on emergency surgery. Major R. V. Patterson of the Marine Corps is well known through his position with the American Red Cross, and Surgeon A. M. Fauntleroy will be remembered for his striking and useful work on the "Medical Aspects of the European War."

"One of the first steps necessary to the work of the new board was to get funds with which to proceed. Chairman Fitzgerald of the Committee on Appropriations, thought well of the idea and the board was given \$2,000, although, curiously enough, it was placed under the nominal control of the Bureau of Labor Statistics of the Department of Labor. Dr. Royal E. Meeker, chief of the Bureau of Labor Statistics, welcomed this new child to his fold, but he readily recognized that the task ahead of the board was one for specialists, and, although the law re-

quires that the board shall act in collaboration with his bureau, Dr. Meeker has been wise enough to give it as free a hand as if it were an independent organization.

"The board is now engaged in collecting expert opinions from a selected group of 5,000 of the best surgeons in the United States, which will enable it to place first aid on a uniform standard basis. A questionnaire covering the main points on which the board desires information has been sent out recently, and already Secretary Rucker is flooded with letters expressing the most cordial endorsement of the standardization idea and promising hearty cooperation. This ready response is really a matter of patriotic self-sacrifice on the part of the surgeons to whom appeal has been made, for each of them will need to give much time and thought to the 61 answers which he has been requested to make. Every sheet of the questionnaire bears at the top the legend: 'Please answer all questions from the viewpoint of what is best in the hands of the layman.' In other words, the board wants to know, not what the surgeon would do in case of accident, but what the injured man or those about him could and should do.

"The work of the Board on Standardization of First-Aid Methods necessarily is twofold. The surgeons who compose the board must first collect and collate the information they receive, and devise their system in accordance with their conclusions, and then they must get this knowledge out to the people. It is the dream of Secretary Rucker that in time a first-aid package, with instructions how to use it, shall have a place in every home in the land. Such a consummation will cost money, and this money must be provided, much of it by the Government, some of it, possibly, through the sale of first-aid kits—although in this connection it might be said that if the Government can afford several hundred thousand dollars a year with which to supply voters with garden seeds it would be equally warranted in sending out first-aid packages. In fact, it is believed that as soon as congressmen appreciate the practical utility of this great scheme for conserving human life they will find a way of their own to pass its benefits around in their districts. The paltry \$2,000 with which the board starts is only a drop in the bucket to what will be needed, but the plan would appear certain to receive enthusiastic popular and congressional support as soon as its features become known."

## MEDICAL NOTES.

**ERADICATION OF HOOKWORM IN BRAZIL.**—Report from San Paulo, Brazil, on November 18, states that the health officers of Rio de Janeiro have announced their acceptance of the offer of the International Health Board of the Rockefeller Foundation to cooperate with the Brazilian government for the eradication of the hookworm in that country. Dr. Lewis Wendell Hackett of the Harvard Medical School has been sent by the Rockefeller Foundation from New York to San Paulo to take charge of the work. The hookworm is extensively endemic among laborers on the coffee plantations in San Paulo, where three-quarters of the Brazilian coffee crop and nearly one-half of that of the entire world is grown. The parasites breed most extensively in the wet, shady soil of the tropical climate. The economic loss to planters due to lack of efficiency on the part of laborers infected with hookworm disease is very great. The anemia of many of these workmen is so profound that they are unable to work more than three or four hours a day. In Porto Rico, where the hookworm has been virtually exterminated by the United States Government, not only has there been a marked reduction of the death rate but the labor output has been enormously increased and the cost of production correspondingly diminished. Instead of thymol it is planned in Brazil to employ the oil of chenopodium in the treatment of the disease. Chenopodium grows as a common roadside weed in eastern United States, but the principal source of production of the drug is in the islands of Java and Sumatra and in the Levant.

**TYPHUS FEVER IN MEXICO.**—During the week ended October 21, 1916, 334 cases of typhus fever were reported in the federal district of Mexico, including Mexico City.

**PREVALENCE OF DISEASE IN VIRGINIA.**—The weekly report of the United States Public Health Service for November 17, 1916, states that during the month of September there were reported in Virginia 16 cases of cerebro-spinal meningitis, 2118 of malaria, 28 of pellagra, 64 of poliomyelitis, 8 of smallpox and 756 of typhoid fever.

**AWARD OF VON GRAEFIE PRIZE.**—It is announced that the German Ophthalmological Society has divided between Dr. Lindner of Vienna and Dr. Ohm of Bottrop the von Graefie prize for the best article published in 1911 to 1913 in the *Archiv für Ophthalmologie*. These articles were respectively on "Miner's Nystagmus" and on "Trachoma and Inclusion Blepharorrhoea."

**RETURN OF AMERICAN PHYSICIAN.**—Dr. Charles A. Powers of Denver, Colorado, has

recently returned to the United States after a service of six months at the American Ambulance Hospital at Paris.

#### EUROPEAN WAR NOTES.

**WAR RELIEF FUNDS.**—On Dec. 2 the totals of the principal New England relief funds for the European War reached the following amounts:

French Wounded Fund .....	\$161,540.38
Armenian Fund .....	107,227.95
Serbian Fund .....	105,291.30
Surgical Dressings Fund .....	58,794.66
Polish Fund .....	49,531.33
Permanent Blind Fund .....	37,108.11
Italian Fund .....	27,873.54
German Widows' Fund .....	25,000.00
LaFayette Fund .....	21,002.53
Russian Refugees' Fund .....	5,667.17
Wittenberg Prisoners' Fund ..	1,889.15

#### BOSTON AND NEW ENGLAND.

**WEEK'S DEATH RATE IN BOSTON.**—During the week ending Saturday noon, December 2, 1916, the number of deaths reported was 232, against 243 for the same period last year, with a rate of 15.90, against 16.93 last year. There were 32 deaths under one year of age, against 31 last year, and 81 deaths over 60 years of age, against 90 last year.

The number of cases of principal reportable diseases were: diphtheria, 40; scarlet fever, 24; measles, 16; whooping cough, 3; typhoid fever, 2; tuberculosis, 40.

Included in the above were the following cases of non-residents: diphtheria, 10; scarlet fever, 6; tuberculosis, 6.

Total deaths from these diseases were: diphtheria, 3; typhoid fever, 1; tuberculosis, 13.

Included in the above were the following deaths of non-residents: diphtheria, 3.

**AN INGENIOUS EVASION OF THE NARCOTIC DRUG LAW.**—The Collector of Internal Revenue at Boston has received reports of several cases where drug addicts have called on druggists and pretended to be internal revenue inspectors. In these cases, the person calling would ask to be allowed to examine the records of the druggist and his stock of narcotics, and while pretending to make the examination would secrete and carry away whatever morphine, cocaine, etc., was available. This has resulted in small amounts of drugs coming unlawfully into the possession of drug addicts and disarranging the records which dealers are required to keep.

Such frauds are entirely unnecessary, because the internal revenue inspectors authorized to examine druggists' records are all furnished with credentials in the form of pocket commissions signed by the Commissioner of Internal Revenue, William H. Osborn, by Deputy-

Commissioner David A. Gates, or by Collector of Internal Revenue John F. Malley.

Druggists should not allow anyone to inspect their stock of narcotic drugs, unless satisfied of the authority of the inspector. In the case of internal revenue drug inspectors, the druggist should ask to see the officer's credential card, in order to avoid impersonation and fraud.

**THE CAMBRIDGE HOSPITAL NEEDS.**—The Trustees of the Cambridge (Mass.) Hospital have recently issued the following appeal for funds describing the work of the Hospital and its needs for the future continuation of its service:

"For thirty years the Cambridge Hospital has been ministering to the needs of the citizens of Cambridge and until now has never made a general appeal for funds to increase its plant and, therefore, its usefulness. The trustees have been fully alive to their responsibilities, however, and additions have been made as funds have from time to time been available from legacies.

"Through a legacy of Mrs. Scollard, in 1913, a large addition was built and the number of beds in the hospital was doubled. A maternity ward also was added.

"These increased facilities have enabled the hospital to care for a much larger number of patients than heretofore, the number for 1915 being one-third larger than that in 1914, and consequently more nurses are required to take care of the patients. The accommodations of the nurses' home are entirely inadequate and the hospital must in some way provide accommodations for these additional nurses.

"An out-patients' building, where preventive and social service work can be done properly, is especially desired. This department is now located in the basement of the nurses' home—the only place which has been available. During 1915 there were nearly 8000 calls for treatment, and satisfactory work cannot be done in such quarters. There is needed \$30,000 for the addition to the nurses' home, \$20,000 for the out-patients' building and \$50,000 for endowment to offset increase in running expenses. Income from our present endowment from patients and donations left a deficit of \$12,376 in 1915.

"One hundred thousand dollars, therefore, are imperatively needed to enable the trustees of the hospital to take care of the increasing demand for its facilities and maintain its high standard of service. Will you not help us either by a gift now, or distributed over two to five years? The sum of \$58,000 has been paid or promised to date from 200 persons and the trustees have broken ground for an out patient building, hoping to have sufficient funds by spring to provide for an improved nurses' home.

"Checks may be sent to James L. Paine, treasurer, Cambridge Hospital Building Fund, 9 Waterhouse Street, Cambridge."

**HOSPITAL BEQUESTS.**—The will of the late Fannie Channing of Milton, Mass., which was filed for probate at Dedham, Mass., on November 27, contains bequests of \$5000 each to the Boston Floating Hospital and the Nursery for Blind Babies, \$2000 each to the Channing Home and the Perkins Institute for the Blind, and \$500 to the Milton Convalescent Home.

**POLIOMYELITIS IN MASSACHUSETTS.**—During the month of November, 179 cases of poliomyelitis were reported in Massachusetts, making a total of 1892 since Jan. 1. Four cases were reported in the first two days of December.

### Obituary.

#### JOHN BENJAMIN MURPHY, M.D.

DR. JOHN BENJAMIN MURPHY, who died of heart disease in Chicago on August 11, 1916, was born at Appleton, Wis., on December 21, 1857. After graduating from the University of Illinois, he received the degree of M.D., in 1879, from the Rush Medical College, Chicago. After practicing his profession for a few years, he pursued his medical studies further in Germany, returning to Chicago in 1884, where he rapidly gained a reputation as a brilliant and ingenious surgeon. It was perhaps his invention of the intestinal button known by his name which, in 1892, first brought him into international prominence. In 1893 he reported to the New York Academy of Medicine his first series of twenty-two cases of cholecystenterostomy for non-malignant disease.

In 1895 Dr. Murphy was appointed professor of clinical surgery at the Chicago Post-Graduate School, and later became chief of the department of surgery in Northwestern University Medical School. He was for many years chief surgeon to the Mercy Hospital, Chicago. In 1898, independently of Forlanini, he suggested the treatment of unilateral disease of the lungs by artificial pneumothorax induced by the injection of nitrogen into the pleural cavity. His name is also associated with the postural treatment of peritonitis, the use of rectal seepage, arterial anastomosis and the extra-articular wiring of fractures of the olecranon. He was highly successful in cartilage and bone grafting and devised an operation for the lysis of ankylosed joints by the interposition of a flap of fascia between the free surfaces of the bone ends.

Dr. Murphy was a member of many medical societies and the recipient of numerous honors. He received the honorary degree of LL.D. from the University of Illinois in 1905, and that of M.Sc. from the University of Sheffield, England, in 1908. He was a fellow of the American College of Surgeons, of the American Surgical Association

and of the Royal College of Surgeons of England. He was a member of the Deutsche Gesellschaft für Chirurgie and of the Société de Chirurgie de Paris. In 1913 he was president of the American Medical Association and of the Clinical Congress of Surgeons of North America.

In 1915 he went to Europe in charge of an American hospital unit serving with the British Army Medical Corps in France. In 1916 he received, from Pope Benedict, knighthood in the Order of St. Gregory the Great. During the last four years of his life he issued the "Surgical Clinics" representing his work at the Mercy Hospital, which have been regularly reviewed in the JOURNAL. Dr. Murphy is survived by his widow.

Dr. Samuel J. Mixer of Boston, at the time of Dr. Murphy's death, gave the following personal estimate of his work and character.

"The death of Dr. John B. Murphy of Chicago, means a great loss to the surgical profession and to the world at large. Possessing an original and active mind, combined with great industry and mechanical and manual dexterity, he has added much to our surgical knowledge and given us new methods of fighting disease and suffering.

"As a writer he was prolific and convincing; as a speaker incisive and enthusiastic. A prominent figure at the meetings of the leading surgical societies, his papers were always listened to with interest and his remarks about the various matters under discussion were pointed and forceful.

"He was an enthusiastic sportsman and thoroughly enjoyed meeting his many friends the world over. He will be mourned and greatly missed."

Soon after Dr. Murphy's death there was incorporated in Illinois, the John B. Murphy Memorial Association, consisting of Drs. William A. Evans, James E. Keefe, Allan B. Kanavel, Frank H. Martin and Frank Crozier. It is the purpose of this Association to raise the sum of \$500,000 as a permanent memorial to Dr. Murphy for the scientific and ethical advancement of surgery.

### Miscellany.

#### THE DOTEN BILL (HOUSE NO. 1015).

An act to establish a System of Insurance to provide Benefits for Employees in Case of Death, Sickness and Accident.

Be it enacted by the Senate and House of Representatives in General Court assembled, and by the authority of the same as follows:

#### PART I.

**DEFINITIONS AND PERSONS INSURED.—SECTION 1.** Recognizing that it is necessary to provide proper care for employees during sickness and pecuniary

support for themselves and their families during periods of inability to work on account of sickness in order to prevent the spread of disease and to protect the health of the subjects of the commonwealth, and recognizing the part which modern industrial and social conditions have in causing sickness among wage-earners, the general court judges compulsory insurance against sickness to be for the good and welfare of this commonwealth and of the subjects of the same.

**Definitions.**—SECTION 2. When used in this act:—

"Commission" means the social insurance commission.

"Association" means a local health or local trade health association, as the case may be.

"Society" means an approved society.

"Carrier" means the society or association which carries the insurance.

"Insurance" means health insurance under this act.

"Disability" means inability to pursue the usual gainful occupation.

"Employer" means a person, partnership, association, corporation, the legal representatives of a deceased employer, or the receiver or trustee of a person, partnership, association or corporation and the state or a municipal corporation or other political division thereof.

"Home-workers" are persons to whom articles or materials are given out to be made up, cleaned, altered, ornamented, finished or repaired, or adapted for sale, in the worker's own home, or on premises not under the control or management of the employer.

"Wages" and "earnings" shall include actual expenditures for or reasonable value of board, rent, housing and similar advantages given employees by the employer and gratuities received in the course of the employment from others than the employer and both these advantages and gratuities shall be added to the actual expenditure of the employer for wages for the purpose of computing his payments under section four of Part III. of this act.

**Compulsory Insurance.**—SECTION 3. Every person employed in the commonwealth for compensation not in excess of one hundred dollars a month, unless exempted under section four of this act, shall be insured in an association or society as provided in this act.

**Persons Exempted.**—SECTION 4. The following persons shall be exempt from the provisions of this act:

Employees of the United States.

Employees of the commonwealth or of municipalities for whom provision in time of sickness is already made through legally authorized means which in the opinion of the commission is satisfactory.

Inmates of charitable or reformatory institutions when employed for the purposes of the institution, with or without maintenance, if provision for maintenance and medical attendance during sickness is made.

Casual employees not employed for the purpose of the employer's trade or business.

Members of the family of the employer who are not paid money wages.

The commission may exempt home-workers, who, owing to the irregularity of their work or other circumstances connected with their work cannot for administrative reasons be included in the system.

**Voluntary Insurance.**—SECTION 5. Self-employed persons whose earnings do not exceed one hundred dollars a month on an average; persons formerly compulsorily insured who, within one year from the date on which they cease to be insured, apply for voluntary insurance; members of the family of the employer who work in his establishment without wages, may insure themselves voluntarily in the local health or local trade health associations of the locality in which they live and of the trade at which they are employed, subject to the conditions of this act.

## PART II.

**Cases in which Benefits paid.**—SECTION 1. Benefits shall be paid for any sickness or accident or death not covered by workmen's compensation.

**Minimum Benefits.**—SECTION 2. Every carrier must provide for its insured members as minimum benefits:—

Medical, surgical and nursing attendance.

Medicines and surgical supplies.

Cash benefits.

Funeral benefits.

**Medical, Surgical and Nursing Attendance.**—SECTION 3. All necessary medical, surgical and nursing attendance and treatment shall be furnished by the carrier from the first day of sickness during the continuance of sickness but not to exceed twenty-six weeks of disability in any consecutive twelve months. This shall include medical, surgical and obstetrical aid to insured women during confinement. In case the carrier is unable to furnish the benefit provided for in this section, it must pay the cost of such service actually rendered by competent persons at a rate approved by the commission.

**Medical Service.**—SECTION 4. The carriers, subject to the approval of the commission, shall make organized provision for medical, surgical and nursing aid by duly qualified physicians, surgeons and nurses or through institutions or associations of physicians, surgeons and nurses, as required by this act.

**Medical and Surgical Supplies.**—SECTION 5. Insured persons shall be supplied with all necessary medicines, surgical supplies, dressings, eyeglasses, trusses, crutches and similar appliances prescribed by the physician or surgeon, not to exceed fifty dollars in cost in any one year.

**Hospital Treatment.**—SECTION 6. Hospital or sanatorium treatment and maintenance may be furnished instead of all other benefits (except as provided in section eight), with the consent of the insured member, or that of his family when it is not practicable to obtain his consent. The carrier may demand that such treatment and maintenance be accepted when required by the contagious nature of the disease, or when in the opinion of its medical officer such hospital treatment is imperative for the proper treatment of the disease or for the proper control of the patient. Cash benefit other than to dependents may be discontinued during refusal to submit to hospital treatment. Hospital treatment shall be furnished for the same period as cash benefit. This benefit may be provided in those hospitals with which the associations and societies have made satisfactory financial arrangements which have met the approval of the commission, or in hospitals erected and maintained by the associations and societies with the approval of the commission.

**Cash Benefit.**—SECTION 7. A cash benefit shall be paid beginning with the fourth day of disability on account of any illness, except for disability due to childbearing; it shall equal two thirds (sixty six and two thirds per cent) of the weekly wages of the insured member. It shall be paid only during continuance of disability, and shall not be paid to the same person for a period of over twenty six weeks in any consecutive twelve months.

**Cash Benefit to Dependents.**—SECTION 8. A cash benefit equal to one third of the wages of an insured member receiving hospital treatment and entitled to cash benefit, shall be paid to his wife, dependent husband or children while he is in the hospital.

**Computation of Benefits.**—SECTION 9. For the purpose of computing the cash benefit, weekly wages shall be taken as the earnings during the last six days on which the employee worked full time preceding disability, not including earnings for overtime, unless such overtime is a regular occurrence in the employment; but if this computation would be unfair to the employee, his weekly wages shall be taken as six times his average daily earnings for the days

actually employed at full time during the three months preceding disability. If any association has established wage classes for any of its insured members, the wages fixed for each class shall be taken as the earnings of all members of the class.

*Periods of Payment.*—SECTION 10. Cash benefit shall be paid weekly where possible, and in no case less frequently than semimonthly.

*Funeral Benefit.*—SECTION 11. The carrier shall pay for the actual expenses of the funeral of a deceased insured member, as arranged for by the family or next of kin, or in absence of such by the officers of the fund, up to the amount of fifty dollars. The funeral benefit shall be paid in case of death of a former member while in receipt of sick benefits, or death within six months after discontinuance of sick benefits provided he has not, within those six months, returned to work.

*Benefits from Other Sources.*—SECTION 12. If the insured member be entitled to benefits during sickness from other sources, his cash benefit under this act shall be so reduced that his cash benefits from all sources shall not exceed ninety per cent of his earnings, and the carrier may refuse to pay cash benefit until the insured member has disclosed the amount of cash benefit to which he is entitled from other sources.

*Payment of Damages from Other Sources.*—SECTION 13. In case the insured member, his heirs or assigns are paid damages from another source on account of sickness, accident or death, the carrier shall be entitled to be reimbursed, by the person to whom damages are paid, for the reasonable cost of all benefits given the insured on account of such sickness, accident or death.

*Suspension of Benefits.*—SECTION 14. (1) While the insured person is serving a term in prison or in jail pending trial, (2) while the insured person is in an insane asylum, home for the feeble-minded, or a public institution for invalid or defective persons, he shall not be entitled to benefits.

*Assignments and Exemptions.*—SECTION 15. Claims for benefits under this act shall not be assigned, released or commuted, and shall be exempt from all claims of creditors and from levy, execution and attachment or other remedy for recovery or collection of a debt, which exemption may not be waived. Benefits shall be paid only to the person entitled or on his order.

*Additional Benefits.*—SECTION 16. The carriers may grant the following additional or increased benefits if the commission be satisfied that the income of the carrier is sufficient for the purpose:—

a. Medical, surgical and nursing care and medical and surgical supplies to members of the family of the insured.

b. A cash maternity benefit to insured women.

c. Extension of cash benefit to exceed twenty-six weeks but not to exceed fifty-two weeks.

d. Funeral benefits for members of the family.

e. Increased amount allowed for medical and surgical supplies and appliances.

f. Increase in the period of extended right to benefit.

g. Dental work in addition to extraction, treatment and ordinary fillings, either up to a certain amount per year or by contribution of part of the cost.

*Extension of Right to Benefit.*—SECTION 17. When contributions cease on account of unemployment not due to sickness, right to benefit shall be extended one week if the insured person has paid contributions during six weeks immediately preceding unemployment, and an additional week for each additional six weeks of paid up membership during the preceding twenty-six weeks.

#### PART III.

*Apportionment of Contributions.*—SECTION 1. The full cost of insurance provided by this act, including

contributions to reserve and guarantee funds, shall be borne by employers, employees and the commonwealth in the following proportions: employers, two fifths; employees, two fifths, and the commonwealth one fifth, except as provided in section two.

*Contributions of Low Paid Workers.*—SECTION 2. If the earnings of the insured are less than nine dollars a week, the shares of the employer and employee of the amount paid by them jointly shall be in the proportion indicated as follows:

If earnings are under \$9, but not under \$8, employer, 60%; employees, 40%.

If earnings are under \$8, but not under \$7, employer, 70%; employees, 30%.

If earnings are under \$7, but not under \$6, employer, 80%; employees, 20%.

If earnings are under \$6, but not under \$5, employer, 90%; employees, 10%.

If earnings are under \$5, employer, 100%.

The contribution of the commonwealth shall remain one fifth of the total.

*Amount of Contributions.*—SECTION 3. The amount of the contributions shall be computed so as to be sufficient for the payment of benefits and the expenses of administration of the association and necessary reserves and guarantee funds.

*Payment of Contribution.*—SECTION 4. Every employer must pay to any local health or local trade health association on the date on which he pays his men, or at least monthly, the total contributions due from him and from his employees to such association. He may deduct from the wages paid any employee the share of that employee in the contribution, which shall be in proportion to his wages, but must inform him, in a method to be approved by the commission, of the amount so deducted. Approved societies shall provide by regulation, to be approved by the commission, for the payment of contributions by their members.

*Calculation of Payments.*—SECTION 5. Payment required from the employer by the preceding section shall be based upon his total expenditures for wages and salaries of employees covered by section three of Part I, of this act during the period for which payment is made.

*Rates of Contributions.*—SECTION 6. In associations in which employees in several industries are insured, payments required from employers of such employees may be fixed at different amounts for different industries, according to the degree of sickness hazard in those industries.

*Establishments with Excessive Rate of Sickness.*—SECTION 7. An association shall have the right, subject to the approval of the commission, to increase the rate of contribution of any employer whose establishment shows an excessive rate of sickness, such additional contribution to be payable by the employer without right of deduction from the wages of the employee.

#### PART IV.

*Division of the Commonwealth into Districts.*—SECTION 1. The commission shall, within six months after this act goes into effect, divide the commonwealth into districts, no one of which shall contain less than five thousand persons subject to compulsory insurance.

*Establishment of Associations.*—SECTION 2. Commission shall, before Sept. 1, 1917, hold one or more hearings in each district, notice of which shall be given by advertisement in at least one newspaper published in the district, and by any other method approved by the commission, and shall thereafter determine whether one or more local health associations and one or more trade health associations shall be established in the district. The commission shall then provide in each district for the election of delegates, half of whom shall be elected by employers, half by employees affected, to conventions which

shall have power to adopt constitutions. The expense of the elections and conventions shall be paid by the commonwealth, as expenses of the commission are paid.

**Consolidation or Division of District.**—SECTION 3. The commission at any time, on its own motion or on the petition of the board of directors of any local health or local trade health association, may consolidate two or more districts or detach a territory from one district and annex it to another, or create a new district from parts of several districts or from one district, already in existence, and shall make such disposition of the property of the dissolved association as shall seem to be proper.

**Establishment of Local Trade Health Associations.**—SECTION 4. Employers whose principal places of business are within the same district and employing two hundred and fifty employees in the same trade, or two hundred and fifty employees employed in the same trade by employers whose principal places of business are within the same district, may petition the commission for the formation of a local trade health association, and the commission, after a hearing within the district, which shall be duly advertised and notice of which shall be sent to the boards of directors of the local health and local trade health associations within the district, may authorize the formation of a local trade health association if there be no other local trade health association within the district for the trade, and if the establishment of the new local trade health association will not impair the solvency of the local health association or of any local trade health association in the district.

**Authorization by Commission.**—SECTION 5. No association shall begin business until it is authorized by the commission. The commission shall authorize an association only after approval and filing of its constitution and after the names and addresses of the board of directors elected for the first year have been filed with the commission.

**Powers of Associations.**—SECTION 6. Associations shall be corporations and shall have all the power necessary to carry out their duties under this act, including the power to verify by audit pay rolls of employer members for the purpose of determining contributions for which employer members are liable.

**Constitution of Associations.**—SECTION 7. Subject to the provisions of this act, the constitution of an association shall contain:—

Name of the association and location of its principal office.

If the association is a local trade health association, designation of the trade or trades for which it is created.

Maximum percentages, in each occupation, of total expenditures for wages and salaries as provided in section four of Part III of this act, at which the regular contribution may be fixed; a maximum which shall not exceed three per cent of the total, except with the approval of the commission, and shall in no case exceed five per cent of the total.

Nature and amount of benefits and length of time during which they shall be given.

Manner of election, number, powers, duties and time of meeting of all committees.

Number, powers, duties and time of meeting of the board of directors.

Method of amendment of constitution, and such other provisions as may be directed by the commission.

**Committee of the Association.**—SECTION 8. There shall be a committee of each association, which shall consist of not less than twenty and not more than two hundred members, to be elected in the manner provided in the constitution, one half by and from the employer members of the fund, one half by and from the employee members. The committee shall cause an audit of the accounts of the association to be made each year, and shall pass upon the same and

upon the annual report and budget of the board of directors.

**Employers' Votes.**—SECTION 9. Each employer member shall have as many votes for employer members of the committee as he employs workmen subject to the insurance and members of the association, except that no one employer shall have more than forty per cent. of the total vote, unless otherwise provided in the constitution.

**Board of Directors.**—SECTION 10. The board of directors shall be elected by the committee for a period of one year. All directors must be citizens of the United States, and a majority of them must be residents of this commonwealth. The board shall consist of not less than eight and not more than eighteen directors, one half of whom shall be elected by employer members of the committee, and one half elected by employee members of the committee. No one shall be a member of the committee and a director at the same time. The compensation of members of the board shall not be more than five dollars a day for each day spent upon the business of the fund. The directors shall be reimbursed for any necessary expenses incurred by them as such directors.

**Powers of the Board.**—SECTION 11. The board shall:—

Fill vacancies in its own number for unexpired terms; provided, that only employers' representatives shall vote for employer directors, only employees' representatives for employee directors.

Appoint all officers and employees of the board and fix their salaries, and may delegate to officers or employees the power of appointing subordinate employees and of fixing their salaries.

Elect a president and secretary from their own number.

Make regulations necessary for carrying out the purposes of the association.

Make contracts with physicians, hospitals, pharmacists and any other persons necessary for the business of the association.

Prepare and submit to the committee annually a financial account and a report for the past year and a budget for the ensuing year.

Represent the association and direct and administer its affairs, except as otherwise specified in this chapter.

**Officers' Bonds.**—SECTION 12. All executive and judiciary officers of the associations shall be bonded for amounts to be determined by the board of directors, with the approval of the commission.

**Reserve.**—SECTION 13. Every association shall accumulate a reserve fund. The board of directors shall transfer to such fund one twentieth of the annual income of the association until such fund is equal to one sixth of the total expenditures for the preceding three years. The fund shall be maintained at this level. Any surplus which may accrue from the investment of such fund may be transferred into the general account of the association.

**Membership in Association.**—SECTION 14. Every person subject to insurance shall be an insured member of the local trade health association of the trade at which and in the district in which he is employed; or if there be no such association, of a local health association of such district; provided, that while he is a member of an approved society he shall be excluded by the board of directors from membership in an association. The commission shall provide by regulation for the case of persons regularly occupied at one trade, but temporarily employed at another. Membership in local health or local trade health associations shall cease as soon as the insured becomes a member of another local health or local trade health association. Any employer shall be an employer member of all associations of which any of his employees are members.

**Voluntary Insurance.**—SECTION 15. A person entitled to voluntary insurance must be admitted on application to membership in the local trade health association of his trade in the district in which he is employed, or if there be no such association, then in a local health association of such district; provided, that any association may prohibit by regulation the admission to voluntary insurance of a person who has not passed a satisfactory medical examination by its medical officers, and that the application for admission be subject to the same condition as an application for insurance. The contribution of the voluntary member shall be equal to the contribution required of the employer and employee for a compulsory member of the same trade and earnings.

**Loss of Voluntary Membership.**—SECTION 16. A person voluntarily insured shall lose his membership if he acquire membership, either voluntary or compulsory, in another association or society, or if he be in arrears for one month in the payment of his contributions, unless this period is extended by the association.

**Fines and Penalties.**—SECTION 17. Associations may fine their employer and insured members and suspend insured members from benefit for violation of their rules or regulations or for fraudulent representations made with the intent of securing or aiding another to secure benefits, in accordance with rules approved by the commission providing for and limiting such fines or suspensions. If an employer fails or refuses to pay any contribution due to the carrier under this act, the carrier to whom the contribution is due may recover the whole sum with interest at six per cent by suit in a court of competent jurisdiction, and the employer shall not be entitled to deduct any part of such sum from the wages of his employee or employees.

**Approved Societies.**—SECTION 18. A labor union, benevolent or fraternal society, or an establishment society, shall be approved by the commission only after hearing the local health or local trade health associations affected and only if:—

It is not carried on for profit, but reasonable salaries paid officials shall not be considered profit.

It is under the absolute control of the insured members in so far as the insurance regulated by this law is affected, except that the employer may appoint one half of the governing body of an establishment society.

It shall satisfy the commission that it is in a sound financial condition.

It grants at least the minimum benefits provided in this act.

It has a membership of at least five hundred persons insured for at least the minimum benefits provided under this act or their equivalent, except that in the case of establishment societies in which the employer satisfactorily guarantees the payment of benefits, the number of members may be fixed by the commission.

Its operation will not, in the opinion of the commission, endanger the existence of any local health or local trade health association.

In case of an establishment society, a majority of the employees subject to insurance request approval, and the employer's contribution be at least equal to that of all the employees.

The approval of the commission may be withdrawn at any time upon its finding, after hearing the society affected, that any of the required conditions are no longer satisfied. The commission may, after a hearing, permit an establishment society to accept, on conditions satisfactory to the commission, as members, all persons subject to insurance in its district.

**Employers' Contributions.**—SECTION 19. The commission shall assess upon every employer, any of whose employees are insured in labor union, benevolent or fraternal societies, a sum equivalent to the employer's contributions had such employees been

members of associations. This sum shall be paid in monthly installments into the guarantee fund established by the commission.

**Contributions of the Commonwealth.**—SECTION 20. The commonwealth shall contribute to every approved society one fifth of its total expense for health insurance under this act, subject to the provisions of section nine of Part V of this act.

**Organization of Wage Groups Permitted.**—SECTION 21. An insurance carrier may, with the approval of the commission, divide the members entitled to benefits into wage groups for the purpose of administering cash benefits.

**Power to Fix Wages.**—SECTION 22. Any carrier may fix the average wages or may fix the average gratuities received in any employment or branch thereof, and on the approval of the commission, such amounts shall be conclusive on all its members, except that the average wages shall not apply to section four of Part III of this act.

**Health Insurance Union.**—SECTION 23. Two or more health insurance carriers may combine for the administration of the medical benefit, subject to the approval of the commission. The commission may, after notice to and hearing of the parties in interest, withdraw its approval and dissolve the union, making such disposition of its property as may seem to it in the best interests of the insured.

#### PART V. COMMISSION.

**State Social Insurance Commission.**—SECTION 1. A state social insurance commission is hereby created, consisting of three commissioners, to be appointed by the governor, one of whom shall be designated by the governor as chairman. The term of office of members of the commission shall be six years, except that the first members thereof shall be appointed for such terms that the term of one member shall expire on January 1, 1918; one on January 1, 1920; and one on January 1, 1922. Each commissioner shall devote his entire time to the duties of his office, and shall not hold any position of trust or profit, or engage in any occupation or business interfering or inconsistent with his duties as such commissioner, or serve on or under any committee of a political party. The commission shall have an official seal, which shall be judicially noticed.

**Secretary.**—SECTION 2. The commission shall appoint and may remove a secretary, at an annual salary of three thousand six hundred dollars. The secretary shall perform such duties in connection with the meetings of the commission, and its investigations, hearings and the preparation of rules and regulations under the provisions of this act, as the commission may prescribe.

**Officers and Employees.**—SECTION 3. The commission may appoint such officers, other assistants and employees as may be necessary for the exercise of its power and the performance of its duties under the provisions of this act, all of whom shall be in the competitive class of the classified civil service; and the commission shall prescribe their duties and fix their salaries, which shall not exceed in the aggregate the amount annually appropriated by the legislature for that purpose.

**Salaries and Expenses.**—SECTION 4. The chairman of the commission shall receive an annual salary of \$4500, and each other commissioner an annual salary of \$4000. The commissioners and their subordinates shall be entitled to their actual and necessary expenses while traveling on the business of the commission. The salaries and compensation of the subordinates, and all other expenses of the commission shall be paid out of the state treasury upon vouchers signed by the chairman or one of the commissioners designated by him for that purpose.

**Office.**—SECTION 5. The commission shall have its main office in the capitol of the commonwealth, and

may establish and maintain branch offices in other cities of the commonwealth as it may deem advisable. Branch offices shall, subject to the supervision and direction of the commission, be in immediate charge of such officials or employees as it shall designate.

**Powers of Individual Commissioners.**—SECTION 6. Any investigation, inquiry or hearing which the commission is authorized to hold or undertake may be held or undertaken by or before any commissioner, and the award, decision or order of a commissioner, when approved and confirmed by the commission and ordered filed in its office, shall be deemed to be the award, decision, or order of the commission. Each commissioner shall, for the purpose of this act, have power to administer oaths, certify to official acts, take depositions, issue subpoenas, and compel the attendance of witnesses and the production of books, accounts, papers, records, documents and testimony.

**Powers of Commission.**—SECTION 7. The commission may adopt all reasonable rules and regulations, and do all things necessary to put into effect the provisions of this act.

**Payment of Commonwealth Contributions.**—SECTION 9.—The commission shall estimate the commonwealth contribution annually before the first day of January of each year and shall, before that date, apportion it among the carriers in proportion to their estimated expenditures for the purposes of the act during the year, and shall notify the commonwealth treasurer of the sum to be paid on March 31, June 30, September 30, and December 31 of the current year to each carrier. The treasurer shall pay the amount out of the unexpended balance of any appropriation in his hands for the purpose.

**Guarantee Fund.**—SECTION 9. The commission shall reserve ten per cent of the contributions of the commonwealth to the carriers and pay it into a fund to be known as the guarantee fund, from which it may contribute for the relief of any carrier, on the application of its board of directors after investigation by the commission. A contribution shall be made only where, in the judgment of the commission, the necessity arises from epidemic, catastrophe or other unusual conditions, and shall never be made where, in the opinion of the commission, the deficit is due to failure or refusal of the directors to levy proper rates of contributions. When, and so long as, in the opinion of the commission the guarantee fund is sufficient, the commission shall make no reservation for this purpose.

**Commonwealth Treasurer Custodian of Fund.**—SECTION 10. The commonwealth treasurer shall be the custodian of the commonwealth guarantee fund, and all disbursements therefrom shall be paid by him upon vouchers authorized by the commission and signed by the chairman or another member designated by him in writing. The commonwealth treasurer shall give a separate and additional bond in an amount to be fixed by the governor and with securities approved by the commonwealth comptroller conditioned for the faithful performance of his duty as custodian of the guarantee fund. The commonwealth treasurer may deposit any portion of the fund not needed for immediate use, in the manner and subject to all the provisions of law respecting the deposit of other commonwealth funds by him. Interest earned by such portion of the guarantee fund deposited by the commonwealth treasurer shall be collected by him and placed to the credit of the fund.

**Report of Commission.**—SECTION 11. Annually, on or before the first day of February, the commission shall make a report to the governor, which he shall lay before the legislature, which shall include a statement of the apportionment, the commonwealth contribution, statistics of sickness experience under this act, a detailed statement of the expenses of the commission, the condition of the commonwealth guarantee fund, together with any other matter which the

commission deems proper to report, including any recommendations it may desire to make.

**Social Insurance Council.**—SECTION 12. The social insurance council shall consist of twelve members, six of whom shall be elected by employer directors and six by employee directors of the local health and local trade health associations; their term of office shall be two years, except that in the first election three of the employer and three of the employee members of the council shall be elected for one year; they shall receive a compensation of five dollars a day for each day spent on the business of the council, and shall be reimbursed for reasonable expenses incurred in connection with such business, to be paid as other expenses of the commission are paid.

**Officers of Council.**—SECTION 13. The council shall elect a president from its own number; the secretary of the commission shall act as the secretary of the council.

**Meetings of Council.**—SECTION 14. The council shall meet during the first week of January, of April, of July, of September, each year. Special meetings shall be called by the president on the request of at least five members of the council or of two members of the commission, at any time.

**Duties of Council.**—SECTION 15. The annual report and recommendations of the commission shall be laid before the January meeting of the council before transmission to the governor, and the council may approve them or make a separate report and recommendations to the governor. All general regulations proposed by the commission shall be laid before the council at a regular or special meeting for discussion before final adoption, except in cases of urgency, to be determined by the commission, and in this case the regulation shall be laid before the next regular meeting of the council or a special meeting called for the purpose.

**Settlement of Disputes.**—SECTION 16. All disputes arising under the act shall be determined by the social insurance commission either on appeal from the proper authority or from the carrier, or, in case of disputes between carriers, by original proceedings. The commission may assign any dispute for hearing and determination to a dispute committee, composed of one employer and one employee member of the council, and a member of the commission, as chairman, the members of the council to serve in turn on the dispute committee for periods of one month; either party may appeal from the decision of the dispute committee to the commission within thirty days from the date of rendering the decision.

**Suits at Law.**—SECTION 17. Suits shall not be brought in any court on any matter on which an appeal is allowed to the commission until after a decision by the commission, or of a dispute committee, and the statutes of limitations shall not begin to run in such cases until after decision of the commission or dispute committee is filed.

## PART VI.

### MISCELLANEOUS PROVISIONS.

**Limitation of Claims.**—SECTION 1. No claim for benefit shall be valid unless made to the board of directors of the proper carrier within one year from the time when the benefit was due.

**Limitation of Claims for Contributions.**—SECTION 2. No claim of a carrier for contribution shall be valid unless suit is brought thereon in the proper court within one year from the time when it was due.

**Disclosure Prohibited.**—SECTION 3. Information acquired by the commission or any association, or any of their officers or employees, from employers or employees pursuant to this chapter shall not be opened to public inspection, and any officer or employee of the commission who, without authority of the commission or pursuant to its rules, or a ther-

wise required by law, shall disclose the same, shall be guilty of a misdemeanor.

**Technical Rules of Evidence or Procedure Not Required.**—Section 4. The commission or a commissioner or deputy commissioner or appeal committee in making an investigation or inquiry or conducting a hearing shall not be bound by common law or statutory rules of evidence or by technical or formal rules of procedure, except as provided by this chapter; but may make such investigation or inquiry or conduct such hearing in such manner as to ascertain the substantial rights of the parties.

**When to Take Effect.**—Section 5. This chapter shall take effect immediately, except that the provisions as to the payment of contributions shall not take effect until January 1, 1917, and the first payment of contributions by the state shall not be made until March 31, 1917; the provisions as to the medical, surgical and nursing benefit and the medicine and supply benefit shall not take effect until April 1, 1917, and the provisions as to the other benefits shall not take effect until July 1, 1917; *provided*, that if a carrier is authorized after January 1, 1917, the provision as to the medical, surgical and nursing and the medicine and supply benefits shall not take effect until three months, and the provisions as to other benefits shall not take effect until six months, after authorization.

**Tax Exemption.**—Section 6. The property of the association shall be free from taxation for all purposes.

#### NOTICE.

**BOSTON CITY HOSPITAL.**—Until further notice, Saturday will be the public operating day at the Boston City Hospital. Operations will commence at 10 a.m., and will be performed by members of the surgical staff on active duty. Operative clinics of individual services will be continued on days to be announced later. In future the operating day of the second surgical service will be on Friday, instead of on Saturday, as in the past. Drs. Lund, Hubbard and Cunningham will operate at 10 a.m.

#### SOCIETY NOTICE.

**THE MASSACHUSETTS THERAPEUTIC MASSAGE ASSOCIATION.**—The next meeting will be held at the Hotel Brunswick, at 7.45 p.m., Thursday, December 14, 1916. Dr. Frank C. Richardson, professor of diseases of the Nervous System, Boston University Medical School, will address the Society on "Dysglandular Syndromes—Conditions of Ill Health from Disturbances of Glands of Internal Secretions."

Members of the medical profession invited.

Please be prompt and thus show your appreciation.

DOUGLAS GRAHAM, M.D., *President*,  
MRS. MABEL F. WALKER, *Secretary*.

#### APPOINTMENTS.

**UNIVERSITY OF GHEENT.**—Dr. J. Versluis, who, since 1907, has been professor of zoology and comparative anatomy at the University of Giessen, has been appointed to the same chair in the new Flemish University of Ghent.

**UNIVERSITY OF NEBRASKA.**—Dr. H. E. Eggers has been appointed professor of pathology and bacteriology; Dr. Amos W. Peters, assistant professor of biochemistry; and Dr. John P. Myers, instructor in bacteriology at the Medical School of the University of Nebraska, Omaha.

#### RECENT DEATHS.

**DR. JOHN A. MCCORKLE**, who died recently at Brooklyn, N. Y., was born at Lordstown, Ohio, in 1847. He received the degree of M.D. in 1873 from the University of Michigan, and later studied at the Long Island College Hospital Medical School. In 1875 he was appointed chemist to the Brooklyn Board of Health. In 1880 he was appointed professor of materia medica at the Long Island College Hospital Medical School, where, in 1886, he became professor of the theory and practice of medicine and of clinical medicine, and in 1904, president of the institution. His specialty was in diseases of the heart and lungs, and he was the author of several books and many papers on these subjects. He was for many years consulting physician of the King's County Hospital, the Norwegian Hospital, the Jewish Hospital, and the St. John's Hospital. He was a member of the American Medical Association, the New York Academy of Medicine, the King's County Medical Society, the Associated Physicians of Long Island, the Brooklyn Pathological Society, and the Brooklyn Society of Internal Medicine. He was not married.

**DR. LOUISE C. PURINGTON**, who died recently at Dorchester, Mass., was born in Madison, N. Y., on July 3, 1845. She received the degree of M.D. from the Hahnemann Medical College in Chicago in 1874, and had practised her profession in Massachusetts since that time.

**DR. WILLIAM MANLY SULLIVAN**, who died recently at North Adams, Mass., was a native of that city. He graduated from the dental school of the University of Pennsylvania in 1904, and began the practice of his profession in North Adams. In 1915 he was appointed a member of the Massachusetts State Board of Registration in Dentistry. He was a member of the Massachusetts and Berkshire Dental Societies and of the North Berkshire Medical Society. He is survived by his widow and two children.

**DR. LOUIS McLAIN TIFFANY**, who died of cardiac disease on October 23, in Mount Custis, Accomac County, Virginia, was born in 1844. He obtained his academic education at the University of Cambridge, England, and received his medical degree from the University of Maryland. He was for many years professor, and finally emeritus professor, of medicine at the University of Maryland and surgeon and consulting surgeon for the Johns Hopkins Hospital, Baltimore.

**DR. HARRY ALBERT TUTTLE**, who died on October 30, at Derry, N. H., was born in Boston in 1875. He graduated from the Harvard Veterinary School in 1898, and since that time had practised his profession in and about Boston. He is survived by his widow.

**DR. WILLIAM UNDERWOOD TUTTLE**, brother of Dr. Harry Tuttle, died on November 10 of pneumonia, at Jamaica Plain, Mass. He was born at Hyde Park, Mass., in 1878, and graduated from the Harvard Veterinary School in 1901. He was not married.

**DR. JULIUS H. EICHBERG**, who died on October 31, 1916, was for many years professor of materia medica in the College of Medicine of the University of Cincinnati.

**DR. JAMES O. GREEN**, who died on November 24, at Long Branch, N. J., was born in 1839. He received the degree of A.B. from Princeton University in 1861, and that of M.D. from Bellevue Medical College in New York in 1864. He had practised surgery for his entire professional career in New Jersey. He is survived by his widow and three daughters.

### Address.

## THE HISTORY OF THE GROWTH OF THE ANTI-TUBERCULOSIS MOVEMENT IN MASSACHUSETTS, AND THE LESSONS TO BE LEARNED THEREFROM.\*

BY VINCENT Y. BOWDITCH, M.D., BOSTON.

IN appearing before you today at the invitation of the founders of this school, I find myself rather at a loss in trying to voice the deep feeling natural to any one upon such an occasion as this. Gratitude to those who have thus honored me by placing me upon the list of those who are to appear in this, the first season of the school; reverence for the memory of the great and good man whose name it bears; a sense of sadness that the wonderful personality which we all loved and leaned upon for sympathy and guidance is now only a memory.—a memory, however, which must always be an inspiration for patient, strong, and unselfish endeavor to alleviate the suffering of others; finally, the earnest desire that I may say or do something worthy of such an occasion to help you from my own experience:—all these thoughts crowd upon me as I stand before you today in the midst of sacred associations which will ever be coupled with the names of Saranac Lake and Edward Livingston Trudeau.

I have been asked to give you the history of the growth of the tuberculosis movement in

Massachusetts, and something of my own experience therein.

In tracing the first active steps taken in our state for the closer study of tuberculosis, it is inevitable that the treatment of the subject should partake of something of a personal nature. I trust that in recording certain facts, I may not be accused of too great filial zeal in mentioning the special work of my father, the late Dr. Henry Ingersoll Bowditch; and I hope, moreover, that I may not be thought egotistical if I bring before you some of my own experiences in these directions during the last twenty-five years while following out and enlarging the scope of certain ideas which were constantly advocated by my father.

Under the tutelage of the great Louis in Paris, in the early thirties of the past century, he imbibed the teachings of Laennec in stethoscopic examination of the heart and lungs. Returning to America, already deeply interested in diseases of the chest, he was pronounced by his contemporaries to be the fitting successor of the then famous Boston physician, Dr. James Jackson, in this special line of work. Early in the fifties, my father began to make laborious investigations, as to the causative factors of pulmonary tuberculosis; at that time existing under the less scientific name of "consumption."

Patient research through the various sections of the state by closely questioning the medical men in every direction, revealed the interesting and important fact that continued residence upon a damp soil was apparently, for some reason possibly not satisfactorily explained, a potent factor in the production of the disease.

\* Delivered at a meeting of the Trudeau School of Tuberculosis, Saranac Lake, N. Y., June 21, 1916.

This work covered a period of eight years, and in 1862 he gave the result of his investigations to the Massachusetts Medical Society, the work being published at that time under the title of "Soil Moisture as a Cause of Consumption," etc. This work was received with acclamation by the Massachusetts Medical Society. A perusal of the pamphlet with its carefully prepared maps and other data convinces one of the immense amount of labor given to the work, and of the apparent soundness of the deductions drawn from his researches.

As an interesting coincidence, Dr. Buchanan of London, almost at the same time published the results of his investigations in England, with practically the same conclusions as those of my father, neither having had previously any knowledge of the other's work. This was twenty years before Koch gave to the world (in 1882) the discovery of the specific cause of tuberculosis: the *bacillus tuberculosis*. Although this discovery gave an unprecedented knowledge of the etiology of the disease, it in no way weakened the importance of the work previously done, for although our modern conception of tuberculosis has been greatly modified by the discovery of the bacillus, I think it may be justly said that clinically we recognize, or should recognize, the fact that although other factors may be equally favorable to the growth of the bacillus, like crowded, ill-ventilated workshops or houses, yet people who live in swampy, low-lying regions seem to be more prone to ill-health in various forms than those who reside on drier, more porous soil, regardless of mere elevation. That such conditions of previous ill-health should be one cause of lessened power of resistance to infection from tuberculosis seems, at least, a plausible explanation of the fact discovered simultaneously by two investigators. Possibly the true reason may never be proved, but we can certainly be guided by what experience has shown to be a clinical fact, and I bring this point up now because, with our present knowledge of specific causes of disease, we are apt to forget the valuable and trustworthy experiences of earlier times.

About the time of which I speak, at Görbersdorf in the mountains of Silesia, the famous Brehmer, who may be called the father of the modern sanatorium treatment for tuberculosis, was beginning to teach the good results upon patients of a properly regulated life in the open air: methods which were at that time ridiculed and condemned by most of the profession, which was steeped in theories involving ideas quite contrary to those taught by him. It is needless to dwell now upon his long and patient work, and the favorable results obtained by him, which have served as a model for succeeding generations and hosts of followers.

Whether at that time Brehmer's ideas had crossed the ocean to special individuals or not, it would be impossible to say today; but an in-

teresting clinical fact which has but recently been brought vividly to my attention, makes it evident that at least one man, over sixty years ago, had prophesied that fresh-air treatment, carried out to a very marked degree, was destined to supplant the methods of that time when patients were shielded not only from cold but even from fresh air; coddled and protected at home; often sent to warm, relaxing climates, and dosed *ad nauseam* with cod-liver oil, whiskey, and other vaunted remedies.

Among my earliest recollections are my father's vehement protests against the close, confined atmosphere of sickrooms. Insistence upon removal of air-tight stoves as the arch enemy of good ventilation, the importance of open windows, of dry cellars, the cutting down of trees which shaded houses too heavily in the summer, and the avoidance of the excessive use of medicines, were all lessons imbibed early and unconsciously by me from their constant reiteration, although I do not recall the suggestion then of our more modern drastic methods, which at that time would have doubtless been regarded as little less than insane by most observers.

In a letter received recently from a gentleman over ninety years of age but still in vigorous health,—a patient who consulted my father in 1857 (nearly sixty years ago) because of incipient tuberculosis,—I have proof that the modern methods had at least entered my father's mind from whatever source. I will not apologize for offering you something of a distinctly personal nature. In my opinion, such examples furnish more vivid proof of the correctness of principles or ideas than pages of mere suggestions, and I should like to impart to you some of the pleasure and profit that I personally received from the words which I now quote, coming as they did unexpectedly.

March 8, 1916.

Vincent Y. Bowditch, M.D.

My dear Sir:—In a conversation, last night, with your friend and classmate, Dr. X., I spoke of a distinct service your father rendered me in the late summer of 1857. After Dr. X. had heard some of my experiences in carrying out your father's directions and the results that followed, he asked me, "Did you ever write and thank him for that service?" I replied, "I did not think of it then, in my confusion, but I have often since, and I should greatly enjoy meeting a son of his and of telling him the happy result of that two hours' consultation, which was my perfect restoration to health in twelve months from well-defined tuberculosis."

Then Dr. X. told me of his pleasant relations with you, gave me your address, and I am greatly enjoying paying a debt, *long past due*, through you to your father's memory.

In that interview, your father strongly disapproved of my going to Key West, as I had proposed, and as strongly expressed his firm conviction that an "out-of-door life on a Minnesota ranch" would speedily bring relief from my ailment. I recall vividly the suppressed vigor with

which he said, "Avoid drugs, hotels, hot stoves, plastered rooms; you can get all these here in Boston and die; yet if you and your young wife have the pluck to go where and do as I tell you, you can live, and live in good health and in a community of immense promise." He walked with me to the door of his office, and patting me smartly on my shoulder said, "Do not fear this cold-air treatment; it is the coming cure for your trouble."

I went, and heartened under his compelling words, I proved his prediction true. Dr. X. seemed to enjoy my narrative of the many severe and cruel tests brought to me and my young wife and child in testing out that "outdoor cure" in a record-breaking Minnesota winter, but the great joy of a perfect recovery outmatched them all.

I can assure you your father's memory has been kept green through all these years. . .

Very sincerely,

Note the last remark made to the patient as he left the office. It has the interesting quality of prophecy in it to us now, surrounded as we are by the frequent proofs of the correctness of those who in recent years at least have believed in and seen the gratifying results obtained in thousands of cases from fresh-air treatment pushed to its limit, and who have felt the stimulus of hope as contrasted with the former heart-sickening sense of depression whenever the word "tuberculosis" or "consumption" happened to be mentioned to the unfortunate victim or to those dear to him.

This point should be emphasized strongly, for, in the midst of doubts and perplexities of practice at the present time, and with the often discouraging attempts to bring tuberculous patients back to health, it is well for those of the younger generation to know the utter hopelessness that often pervaded the minds of patients, their friends, and even the physicians themselves, before more modern methods were begun. I feel, now, grateful for my own experiences of former years, for it gives me the greater courage in speaking of the vastly improved methods of dealing with tuberculous patients of today, and I say this in the face of the statements of a few pessimists who decline to believe that the undoubted decrease in the mortality from tuberculosis has any connection with the modern methods of treatment and who are inclined to believe that our efforts are fruitless in that direction.

Just here, however, it would be well to speak of the necessity for conservatism in all enthusiasm for new projects and ideas. It was said of the great Pasteur that he was continually clipping the wings of his transcendent imagination lest it should lead him astray while lifting him to regions higher than before. He rigidly tested his conclusions before submitting them to final proofs and cautioned others to do the same, for he saw the danger of claiming too much lest discredit should fall upon an idea which, while marking a distinct advance, was possibly far from perfect.

The growth of the idea of sanatorium treatment for tuberculosis is a marked example of this. Its earliest advocates, who knew how much could be accomplished by it and who continually urged this method, knew perfectly well that it was not a panacea for every case, and continually urged conservatism even in their enthusiasm for it. Many over-zealous workers, however, among the profession and the laity, deceived by the favorable results, sometimes only temporarily obtained by sanatorium treatment, jumped at conclusions, and even rushed into print with extravagant claims in spite of the protests of those who knew better. The inevitable result followed: a reaction from unhealthy enthusiasm over a new idea and a corresponding swing of the pendulum to an equally extravagant degree in the other direction, with detriment and injury—fortunately, however, not permanent—to a cause which had been proven of great benefit to humanity.

Soberer judgment in recent years, however, has brought this subject back to a more normal point, and to those who know that tuberculosis, to be overcome, must be attacked by every method known to science, there is now no shadow of doubt that one of the most important of these is the establishment of sanatoria for suitable cases, where, under favorable conditions, thousands of patients may be restored to health who in former years would have run the usual fatal course, unaided and hopeless.

Trudeau, as most of you know, founded his now famous institution in 1885, as the first of its kind in America. Encouraged by his example, and having in mind the often expressed wish of my father in former years, that he had some place in the country near Boston where he could send tuberculous patients with benefit, I soon afterwards conceived the idea of establishing a small institution not far from my native city for this purpose, to be used for those who could not afford to seek distant health resorts. At that time, it was thought to be a *sine qua non* of recovery from tuberculosis that high altitudes far from the sea should be sought. The idea that it could be cured at a low altitude not far from the sea, and in the harsh inclement New England climate was regarded by many as little short of chimerical.

In spite of many discouragements, however, in 1889, money was obtained from interested people, and a small farm was bought in Sharon, Massachusetts, eighteen miles from Boston, situated on the watershed between Providence and Boston, only 250 feet above sea level, on gravelly soil and abounding in pine woods. With a sufficient sum of money assured to begin with, a small but suitable building for eight women patients was erected and on February 9, 1891, just twenty-five years ago, the Sharon Sanatorium opened its doors as a semi-charitable institution, the first of its kind in New England, and [up to that time the only one in existence for

this special purpose under the above-mentioned conditions of altitude and climate.

Begun largely as an experiment hitherto untried, facing the natural doubt in the minds of many of the medical profession and others as to its ultimate success, the work naturally involved close observation combined with keen anxiety as to the outcome. It was not long, however, before favorable results in a fairly large percentage of early cases began to impress those who doubted at first. By continued observation in after years and by improved methods of treatment, the favorable results increased in number, finally leaving no doubt as to the success of the experiment begun years before. Since 1891, the sanatorium has steadily increased its capacity, and in this twenty-fifth year of its existence its work will be enlarged and broadened by the establishment of a combined school and sanatorium for tuberculous children. As each year goes by and favorable reports still come from those who years ago left the sanatorium with apparently renewed health, the success of the experiment is shown more and more satisfactorily. The fact, moreover, that this and every other sanatorium of similar nature, if properly regulated, acts as a school of hygiene for the patients and through them to the communities in which they live, I believe to be the most important feature of such work; for in bringing our patients back to health, we also teach others through them how to keep well; a potent factor in the cause of preventive medicine and one often not sufficiently recognized in considerations of the subject.

Dr. Alfred Worcester, of Waltham, Massachusetts, who had watched the work at Sharon in its early years with keen interest, was appointed a trustee of a proposed new state hospital for advanced consumptives, afterwards opened at Rutland, Massachusetts. Largely through his influence and in consequence of the favorable results noted at Sharon, as stated in the first report of the Rutland institution, the purpose of the new hospital was changed to that of a sanatorium for the treatment of early and hopeful cases of tuberculosis. In October, 1898, this institution was opened; the first state sanatorium of this nature in the United States, and to which I had the privilege of being attending physician for the first eight years of its existence.

From this time on, the anti-tuberculosis movement seemed to go forward by leaps and strides, spreading over the country. In 1898, Dr. Charles Millet of Brockton, Massachusetts, began a series of experiments with what may be called the first examples of "home treatment" among poor people, most of them mill and factory operatives who were dependent upon their own efforts for support. His admirable work in teaching his poor patients to build small, open sleeping balconies at their homes, to be utilized at night, was really the beginning in substantial measure of similar, but more elabor-

ate methods in later years under the supervision of Dr. Joseph H. Pratt in Boston, and afterward his able co-worker, Dr. Nathaniel K. Wood, both of whom have published the favorable results obtained from so-called "church classes for tuberculous patients" under the charge of the Emmanuel and Arlington Street churches respectively. In 1900, Dr. Millet established in his ancestral home in East Bridgewater a sanatorium for well-to-do patients, founded upon the same principles as those of its predecessors, and within the last decade, two private sanatoria for the more favored class of patients have been established at Rutland, Mass., by Drs. Bayard T. Crane and George N. Lapham.

In 1904 the first attempt was made for dispensary supervision of tuberculous patients in Boston at the Boston Dispensary, under the guidance of Dr. E. O. Otis. This was founded upon the principle first suggested by Dr. R. W. Philip, now Sir Robert W. Philip, of Edinburgh, and of Prof. Calmette of France, who first gave their methods to the medical world in the eighties. By these means, the plan of caring for tuberculous patients at their own homes, and in the out-patient departments, was established. This plan, which was adopted so successfully by Philip and Calmette, never was developed to a large extent here, however, until recent years. It has been greatly elaborated since the establishment of the Boston (Mattapan) Hospital for Consumptives, founded in 1906, with its large out-patient clinic, situated in the heart of Boston and under the central control of the municipal authorities and the medical staff. Not long after the establishment and growing success of the Rutland institution, it was my strong personal conviction, and that of others, that in order to work towards the greater control of tuberculosis, hospitals for the more advanced cases must be erected throughout the state, and a strong sentiment arose in favor of the plan. Public interest had been steadily aroused, and, in 1907, nine years after the opening of the Rutland sanatorium, the erection of the large hospitals, now at North Reading, Lakeville, and Westfield, was authorized by our legislature. At first, these partook, as intended, of the nature of hospitals for very ill patients, but with the steady growth of the anti-tuberculosis movement and the realization that towns and cities should erect their own local hospitals for such cases, the character of these last-mentioned institutions has recently changed again, the object being to devote them to the more hopeful cases. The sanatorium at Westfield is now being used chiefly for women and children.

In 1907, the Prison Camp at Rutland, for the reception of tuberculous inmates of Massachusetts prisons, was founded.

The Boston Association for the Study and Prevention of Tuberculosis, founded in 1903, was another proof of growing public interest.

Composed of physicians and laymen, its example has been followed in many places throughout the state. It was instrumental in founding a "Day Camp," the "Prendergast Camp" in the suburbs of Boston, and also the second school in the country for tuberculous children, as well as other important features in anti-tuberculosis work.

During the past three years, the Massachusetts Anti-Tuberculosis League, an outgrowth of the original Boston society, was begun. The object of this latter association is to bring together the various anti-tuberculosis societies at stated periods, to compare conditions and results of work, thus encouraging coöperation of the various societies which are actively working throughout the state, and to spread by individual effort in special communities knowledge of the disease and the means of overcoming it.

The movement in Massachusetts has received a great impetus in the past three years by the establishment of a Board of Health Commissioners, which has replaced the former State Board of Health. Under the guidance of the chairman of the Board, Dr. Allan J. McLaughlin, strong influence has already been brought to bear toward enforcing laws relating to the tuberculosis question, notably those which compel any town of 10,000 or more inhabitants to establish dispensaries, and every city of 50,000 or more to build hospitals for the reception of far-advanced cases, thus doing away with the necessity of taking such patients far from their homes and friends, and at the same time removing sources of infection from the crowded and poor districts. The more recent law for the erection of county hospitals in communities of under 50,000 inhabitants, at the rate of one bed to each two deaths, is also being enforced.

At the present time, ten of the twelve cities in Massachusetts of 50,000 inhabitants or over have hospitals for advanced cases, some being under private management; four cities of under 50,000 have hospitals; and there is one county hospital in Hampshire and another already authorized for Barnstable County.

Fifty-four of the cities and towns of 10,000 inhabitants or over have now dispensaries established. Mention must be made also of the erection of separate wards or buildings for the tuberculous insane.

The Commissioners of Health are also endeavoring to bring about a more rigid enforcement of the law requiring physicians to register their cases of tuberculosis; and during the past winter the first attempt has been made, thus far unsuccessfully, to pass a law for the control of the incorrigible consumptive.

In reviewing what has been done in these matters in the last few years, when grappling with one of the most difficult problems known, one can feel only the greatest satisfaction, coupled with the belief that, with time and inexhaustible patience and persistency, tubercu-

sis can be relegated not only to the list of diseases under control, but to the list of those which are preventable. This cannot be done, however, without the active co-operation of every physician in following out closely the teachings of past years. There has been surprising and discouraging apathy and indifference up to comparatively recent times in these matters; hasty and careless diagnoses; neglect in watching symptoms which are known now to be strongly suggestive of tuberculosis, even when active signs may not be present; failure to make sputum examinations and to report cases of tuberculosis to health boards; lack of care in teaching the patients and their families the danger of infection and how it may be avoided, at the same time warning them against the wrong and harmful spirit of terrorism. All these shortcomings retard the successful outcome of the tremendous efforts now being made far and wide to lessen the ravages of this disease.

It is an encouraging thought, however, to mark, apart from what is being done in Massachusetts, the gradual change of feeling in these matters everywhere, and especially inspiring to note the enthusiasm with which this new movement at Saranac Lake has been met. The quick response to the announcements of this school should bring courage and hope to all of those who are deeply interested in it. It is you who can now act as missionaries in this great movement throughout the communities in which you live, not only in the profession but among the laity.

In the foregoing remarks, I have endeavored to give you some idea, although necessarily an imperfect one, of what has been done in my own state. With each month that passes, some new work is begun, and at the close of each year all that has been accomplished serves to make the previous record seem like ancient history. It all proves, however, the fact of the strong determination that is already increasing among our people to overcome the disease which causes the largest death rate in the civilized world.

Only by absolute patience, by dogged perseverance, with our present knowledge of the disease and its remedy, can we make progress. Let us not be deceived by the belief that the end can be gained in any given number of years. The experience of those who have been working in the State of Victoria in Australia, as told us by Dr. Victor G. Heiser, our former Health Commissioner in the Philippines, in an address last year, should give us courage to feel that possibly we can do likewise, even though our social conditions may make the task more difficult than in countries where they may be less complicated than here. The results claimed by them, as testified to by Dr. Heiser in the *Journal of the Out Door Life* of January, 1916, should be read by everyone, for they contain details of procedure which must be faced in our own country if we hope to gain the success claimed

in Victoria. Chief among these details comes the registration of every case of tuberculosis by the health authorities, which involves absolute adherence to the law which now exists with us (but is not obeyed as it should be), viz., that every physician shall report to the local board of health and to the state health commission all cases of tuberculosis. Another item, already mentioned, is the care and control of the incorrigible consumptive who, regardless of laws, of his own health and that of others, persists in spitting indiscriminately everywhere and indulges otherwise in filthy habits. Our people have not yet been brought to the pitch of insisting that such laws shall be enacted; laws which, while somewhat drastic, can be made consistent with kindness and justice to the individual, and to the community. Four states in the Union, viz., New Jersey, New York, Wisconsin, and Minnesota, have made laws for this purpose, which vary in their scope. How thoroughly these laws are being enforced, however, is a matter of doubt.

The attempt made last winter to pass such a law in our Massachusetts legislature failed, as expected, because of lack of proper knowledge of the subject among not only the legislators themselves but the people they represent. Here is another of the many details of missionary work in which we all as intelligent physicians should take part.

A knowledge of the history of medicine is of great importance to every student, that he may learn through the experience of others facts which shall make him better prepared for the practice of his profession in whatever branch he may have chosen. Having given you a very brief history of the growth of the anti-tuberculosis movement, I trust it may be helpful to you if I now give you something of my personal experience in this branch of medicine, covering a period of over twenty-five years. One learns, after years of practice in methods of treatment, that a judicious amount of scepticism to temper the earlier enthusiasm is always best, provided that one, while having a reasonable hesitation in accepting new ideas immediately, does not fall into an attitude of conservatism which may blind him to the merits of what is new and possibly useful.

I have been long enough in practice to witness the rise and fall of many a vaunted remedy for tuberculosis. Most of them have had their day only to be put, rightly, into oblivion. Some of them have had a certain amount of merit, "the grain of wheat in a bushel of chaff," and may be utilized as such. While still holding to the hope that we yet shall discover some specific remedy for this disease as in others, that may lessen its ravages, I find that thus far what we call the hygienic care of the patients is the chief factor in all treatment, such as is now made use of in all properly regulated sanatoria: fresh air pushed to its limit, the judicious use of rest and

exercise, proper diet, and close observation of the patient during the active stage of the disease.

Serums, inhalations, injections (both rectal and subcutaneous), even drugs, have been tried many times, only to fall into disuse, though a few of them have proved useful as adjuncts to other treatment. After a long-extended conservatism, however, as to the wisdom of its use, I have come, after careful observation of patients who had seemed to resist the ordinary methods of treatment, to the position held by Trudeau: that in selected cases the cautious use of tuberculin is not only beneficial and lessens the liability to relapse, but that it is often followed by complete arrest of the disease as shown by subsequent histories. That it should not be used indiscriminately, and should always be under close supervision, is my firm opinion. I cannot recall any case in which I could trace harm to the patient from its careful use, although in some it has been discontinued because of some possible discomfort or failure to note special improvement after several weeks of trial. The forms employed at Sharon are those either of the old tuberculin or the "bouillon filtré" of Dénys.

As to the use of artificial pneumothorax, our experience at Sharon would seem to show quite marked improvement, occasionally surprising, in certain cases of fairly well-advanced disease when ordinary measures had failed to produce marked results. This has not been always the case, however, and whether this method of treatment will be as frequently resorted to in the future as some of its advocates prophesy, we feel to be, in the present stage of its development, a matter of doubt.

Let me now give you something of my own personal experience in determining the presence of tubercular disease in its pulmonary form. The day of hasty diagnosis in any suspected case is past and there can be no excuse for the lack of proper and thorough examination of the patient when suspicious symptoms are present. Of paramount importance is the previous personal history of the patient, which often throws a flood of light upon conditions which may be shrouded in doubt. Given a history of malaise for several weeks or months, loss of flesh, possibly slight feverishness, accompanied or not by cough, *watch your patient* carefully and examine his chest from time to time and note if there are any departures from the normal there. Cough is, of course, a suspicious symptom, and if sputum appears it should be examined immediately, keeping the established fact in mind that repeated negative examinations do not prove the absence of tuberculosis. If, upon percussion of the chest, you find a difference of pitch in the apices, or even slight dullness, *note the fact* and watch your patient, while keeping in mind the normal difference often found in healthy individuals in the apices of the lungs.

If there is a difference in the character of the respiration in the two lungs, or a single r  le at one or the other of the apices, be still more suspicious of incipient trouble. Modern science and observation have taught us that pathological conditions other than tuberculosis can cause, possibly, apical changes, but the weight of evidence is in favor of regarding such conditions as danger signals which must not be disregarded. Personally, in accordance with my earliest teaching, I have found that such signs, coupled with systemic symptoms of fairly long duration, are, in the majority of cases, significant of early pulmonary tuberculosis, as proved by subsequent histories.

As to haemoptysis, the weight of evidence by most observers seems to show that in the great majority of cases it is a signal of incipient tubercular disease, even when physical signs are lacking; to which opinion I agree, but from long observation I regard the appearance of blood as less grave, as far as prognosis is concerned, than other symptoms more significant of active systemic disturbance. To determine the exact causes of abnormalities in the lungs, with an accompanying enfeebled condition of the patient, often taxes the power of the observer to the utmost, and even the most skilled clinician may in some cases be unable to make a definite diagnosis. To lay down absolute laws, moreover, in teaching others how we have reached our own conclusions in a difficult case, may be next to impossible.

I shrink from making excursions into the realm of mysticism, but I believe that there often comes after long experience an intuition or instinct, by whatever term we may call that sense of conviction which we cannot put into words or possibly explain to others, but which helps us to reach our conclusions,—a dangerous faculty to depend upon too much, but which I think we must confess exists to a greater or less extent in every physician of long experience in his dealings with disease.

The use of the x-ray has of late years come markedly to the fore in examinations of the chest. With all the enthusiasm that is natural to a new and fascinating study, there is no one method which should be treated, in my opinion, with more conservatism than this. It is gratifying to notice this spirit among those who are experts in roentgenology; for, while thinking it to be a valuable adjunct in the diagnosis of disease of the chest, I believe the errors arising from its use by one of slight experience are too great to warrant its being resorted to by tyros as a certain means of diagnosis. That further developments may show it to be of even greater value than now is quite possible, but on no condition should it be considered the one determining factor as to the presence or absence of pulmonary tuberculosis. More than one striking example of hasty diagnosis on the x-ray alone, involving serious mental distress to patients

who have presented no general symptom of pulmonary disease, has been brought to my attention,—a fact which makes me emphatic in my disapproval of conclusions based on this method alone.

Notwithstanding the fact that we have made a marked advance in the past few years as far as the successful treatment of tuberculosis is concerned, we have even a greater work before us in the field of preventive medicine. We are coming more and more to the belief that tuberculosis is a disease of childhood, which often lies latent, unsuspected until adult life, and then bursts into activity because of some acute exciting cause. It behooves us, therefore, to begin early to fortify children against disease by increasing their powers of resistance in every way possible. Pure milk, the adoption more and more widely of open-air schools even for well children, are among the most important factors in guarding against the development of tuberculosis. Proper housing, as a contrast to conditions often found (not alone in our poorer districts), thorough ventilation, and cleanliness in all workshops and factories, are equally essential and must be insisted upon if we wish to eradicate this disease.

As a concrete instance of the value of sanatorium instruction in the line of preventive medicine let me cite one case which bears directly upon this point. Not many weeks ago a woman who graduated from the Sharon Sanatorium thirteen years ago, and has been a most loyal friend ever since to the institution, came to my office to tell me of her subsequent history of good health and active work as a public school teacher in one of the largest manufacturing cities in Massachusetts. Sixteen years previously she had come to Sharon to remain as a patient for three years, frequently a source of despair to us because of repeated appearances of tuberculosis in varied forms. By persistent effort she finally regained her health and left with the disease completely arrested, and began again her duties as teacher and has continued them with scarcely an interruption since. Not long ago she wrote me—"I am better than ever before, and I lose no opportunity of teaching my children what I learned while at Sharon, the value of fresh air. During the past winter I have had the windows of my school room almost continually open, and I have not had one child away from school during the season on account of illness, as against epidemics of 'colds' among the children of most of the other public schools in this town."

This is but one of the many striking examples of what can be done in the way of missionary work by those who have fought the disease themselves. Such testimony as this should give us hope and courage for the future.

In conclusion I linger over the memories of him whose name this school bears, and I obey the strong impulse to tell you the thoughts which come to me whenever I recall the life and work

of the beloved leader, master and friend now gone. We are passing through a terrible crisis in the history of the world. Every day brings to us some horrible tale of blood and carnage. Thousands of gallant young lives are daily being sacrificed; tales of noble, unselfish heroism are told over and over again, and emphasis is laid upon the wonderful latent attributes of human nature that are brought out in the midst of the horrors of war. All honor to those who thus give their lives to an ideal! But let us not forget the great army of those who, with no thought of personal glory, go bravely forth each day through months and years of patient, strong endurance, facing death by disease with cheer in their hearts and a smile on their lips. There are thousands of moral heroes too who brave the harsh criticism of the world while suffering mental anguish unknown to most of their fellow men, and who cheerfully endure for the sake of their ideal. Greatly as I honor the "heroes of war," my sense of reverence for the "heroes of peace" is even greater. Of such was Edward Livingston Trudeau. Always to be associated with the memory of him, come vividly to my mind the beautiful lines of a modern poet who, had he written nothing else, would yet be entitled to high rank among makers of verse.

"A picket frozen on duty,  
A mother starved for her brood,  
Socrates drinking the hemlock,  
And Jesus on the rood;  
And millions who humble and nameless  
The straight hard pathway plod—  
Some call it Consecration  
And others call it God."

### SIIOCK AT THE FRONT.

By W. T. PORTER, M.D., BOSTON.

(From the Laboratory of Comparative Physiology at the Harvard Medical School.)

#### I.

In July, 1916, I received a letter from the Rockefeller Institute for Medical Research asking me to go to "the front" in France or Belgium, in the hope that studies upon freshly-wounded soldiers might advance our knowledge of traumatic shock and lead to its prevention or cure. Dr. Carrel had written from Compiègne that many thousands died from traumatic shock and that a remedy was urgently needed.

I reached Paris July 20, and, after the usual delays in obtaining a permit for the Army Zone, I proceeded to the wonderful hospital at Compiègne—a hospital in which suppuration, hitherto sadly inevitable and in war almost uni-

versal, has once for all been conquered. In this place, the genius of Carrel and of Dakin, and the penetrating intelligence of *Compte Du Nouy* have added a very glorious chapter to our knowledge. From Compiègne I went to La Panne in Belgium. Here, forty minutes from the trenches, Dr. De Page, a rare administrator and most able surgeon, has created an "ambulance" of 600 beds, perhaps the best of all the large hospitals near the fighting line. Through Dr. De Page, I became the friend of General P. and Colonel D., of the ——— brigade of French infantry, who invited me to visit them at Nieuport, where they were holding the sector along the river Yser. Here I remained some time, making observations in the trenches and in the postes de secours. Upon returning to La Panne, I was on duty in the receiving ward. The blood pressure was examined in all the wounded brought in during sixteen days and nights. Further observations were secured at Verdun and on the Somme.

Very early in this investigation, it was evident that my immediate duty was to study low blood pressures, from their onset until the death or recovery of the wounded. Two very practical questions were to be answered: Are the phenomena of low blood pressure in wounded men essentially those observed experimentally in laboratory animals? If so, can the lives of the wounded with low blood pressure be saved by the remedies which save the lives of animals with experimental shock? Obviously the first step was to determine whether life in the trenches, under bombardment, of itself lowers the arterial pressure or predisposes the soldier to a failure of the pressure after he is wounded. It was for this that I went to Nieuport.

Nieuport lies upon the Yser. When war broke out, the town contained about 4,000 inhabitants. Not one remains. Its handsome church, its historic tower, are totally destroyed. Nor has a single house escaped. Every day, shells fall in its streets, and crumbling walls crash down, adding fresh ruin to a scene most desolate. The town and the trenches on the opposite bank of the Yser are held by some thousands of French soldiers. Naturally, everyone lives in a cave; in the town, a cellar made proof against all but heavy shells; in the trenches, a hole dug in the earth.

By day, the streets are almost deserted. With the dark, the scene changes; the streets fill with men; horses and carts appear; and every man and every cart carries a burden; beams, baskets, ammunition, bags of chloride of lime, wicker supports for the sides of the trenches, cement, and a hundred other articles. Meanwhile, the bombardment goes on. Even when the communiqué reports "perfectly calm," there are in each regiment at least five or six wounded every twenty-four hours. It seems a small loss in a regiment of 2,500; yet this never-ceasing drain is even more important than the

spectacular "offensive." Five or six men a day is 2,000 men a year. No man can foretell when his turn may come. In fine weather, the Colonel, three officers, and myself, used to lunch and dine in one corner of a ruined court. In the course of ten days, two shells fell in that court, both at the end containing the cook-stove. At that end not a square foot escaped its piece of broken steel. But the stove was in a small recess, and the chef was near the stove. His deserts were great and he escaped uninjured. Such accidents happened everywhere in Nieuport. In the trenches, naturally, it was worse. There should have been a constant strain. It was, therefore, with the greatest interest that I undertook a study of the blood pressure under these novel conditions.

These studies began at the place most likely to yield a result, namely, in the first line trench, 38 metres from the Germans. It was a strong work, heavily reinforced with sandbags and well provided with machine guns. Through a periscope, the German line seemed strangely near. Absolutely silent, except for shell fire, it stretched across the unkempt fields as far as the eye could reach. Deserted though it seemed, to lift a head above a parapet was almost always fatal. The soldiers who held our trench were very cheerful. They bared their arms and watched the record of the blood pressure with smiles. Except that everyone spoke in a low tone and kept well against the front wall of the trench, we might have been in Paris. The arterial pressures were normal. Half an hour afterwards, an officer in that trench was shot through the head.

I made a careful study of the men under all the conditions of their apparently abnormal life, in the trenches, the batteries, the observation towers, and in their sleeping quarters. The food was good. The coffee and soup were hot even in the first line. The bread was excellent. I went to the company kitchens and fished the meat out of a kettle in which was cooking the stew for 200 men. It was all that could be desired. The latrines, which furnish an admirable index of military efficiency, were beyond criticism, even in the trenches. I went into every latrine to be found within a square mile; they were all well lined and inoffensive. The sleeping quarters, to be sure, were dark and often damp. Poor Colonel D. kept a stove going day and night near his bed and even then his cave was wet. Yet in this whole regiment, there were practically no sick. At first, I could not believe this. But as I slept with the regimental surgeon, in a black hole under a fallen brewery, the health reports were soon at my disposal. The official health return was convincing evidence. This amazing efficiency was due to the good food, the wonderful *esprit* of the officers, and the fact that the regiment was kept in Nieuport for periods of eight days, after which the men were rested an equal period at

Ost Dunkirque, where they could live above ground, though still exposed to occasional shell fire.

It is important not to judge a soldier from the standpoint of a civilian. Life at Nieuport is just as normal as life in Boston. It is different, to be sure, but well-fed men commanded by trusted officers speedily accustom themselves to the difference. Near the cellar in which I slept was a small garden, pleasantly decayed. I used to sit here under a pear tree, reading, while the Germans tried to find an annoying battery of "seventy-fives" two or three hundred yards away. Shells flew overhead sometimes at the rate of four or five a minute, but no one minded them. It was perhaps dangerous, but not very dangerous, and it was as safe there as anywhere else. The point to be made is that being under fire soon gets to be a matter of course. There is nothing in this to affect even the heart beat, much less the more stable arterial pressure.

My observations, therefore, do not support the view that soldiers under fire suffer from low arterial pressure.

The artillery fire preceding and during an attack is, of course, much more severe than the habitual bombardment. To get blood pressures during an attack, I went to Verdun, where my post was a wretched cellar at the Mort d'Homme. More than 20,000 wounded had passed through that cellar—a wet, dirty, black, verminous hole, in which one could scarcely stand upright. But at the time of my visit there was no offensive; the re-capture of Donauumont was some weeks later. After Verdun, I asked to be placed in a column of attack at the Somme. My application was backed by the highest civil authority in France, but "Grand General Headquarters" would not hear of a neutral mixing in that business. Here I got no nearer than a clear view of the aeroplanes, the sausages (stationary balloons) and the smoke of the guns. Close questioning of the officers of the Nieuport regiment, which had been in the worst of the great German drive against Verdun, made it clear that a storm of eight-inch shells is not an indifferent matter. There is some emotion. It is possible that such emotions may affect the heart beat, but there is at present no evidence and no probability that the blood pressure is materially lowered. Indeed, we are led to expect that the excitement would raise the blood pressure rather than lower it.

The air pressure from the explosion of large shells sometimes shakes the nerve cells so violently that their functions are, so to speak, shaken out of them. Paralysis, low blood pressures, and other injuries may be thus produced in men who have no visible wound. The treatment of these low blood pressures does not differ from the treatment of those following wounds, but the prognosis is probably less favorable.

Experiments made with Dr. Story (Porter, W. T., and Story, T. A., *American Journal of Physiology*, 1907, xviii, p. 184) in 1906 showed that when an animal received a blow on the skull, the general blood pressure fell to 33 mm., but soon rose again to the normal. Thirty millimetres is the level to which the pressure sinks on removal of the spinal cord. Similar effects are seen in soldiers from the air pressure of exploding shells. In Amiens, I examined cases in which the low blood pressure had continued several days but with ultimate recovery.

Serious injury is also produced by the inhalation of the hot gases liberated by the explosion,\* but I have no data as to the effect of such gases on the blood pressure.

The usual history of a wounded man with low-blood pressure may be learned from one of the cases which fell under my own observation. A shell explodes in a first-line trench. The fragments tear the thigh, breaking the femur; the arm is also wounded, and some small pieces of steel enter the back here and there. The brancardiers (stretcher-bearers) quickly arrive, the man is placed on the stretcher, and borne to the poste de secours. As the first line is a mile from the poste and the trenches are narrow, progress is difficult, especially when the stretcher meets great cans of hot food slung from a pole resting on the shoulders of two men. At the poste, the wounded man is carried down some steps into a cellar, his wound is covered with a bandage, and he receives an injection against tetanus. Meanwhile the ambulance has appeared. The stretcher is placed on the rack in the ambulance, and I am placed at full length on another stretcher alongside the wounded man. The ride to the nearest temporary hospital begins. The road is rough, especially where it has been pitted with shell fragments. I find the jolting painful, but the wounded man is too far gone to groan. Our feet are next the curtain which attempts to close the rear end of the ambulance. A cold draught chills them. I reflect that as the patient is on the verge, this additional exposure may finish him. After almost an hour, the ambulance runs over cobblestones, even rougher than the country road, and we reach the *Pavillon de Réception*. A cry of "blessé" is heard. Brancardiers run out, the wounded man is carried into a large ward and laid on the floor. Orderlies appear with one large bag for his clothes and one small bag for articles from his pockets. He is placed on a bed, largely stripped, and washed. After a few minutes the surgeon appears. He finds the man with eyes turned up until only the whites are visible, the skin cold, the face muddy parchment, the heart frequent and feeble, almost no pulse at the wrist. Hot bottles are put in the bed. An intravenous injection is ordered. An ice-cold flask containing 1000 cc. normal saline

solution is put in a pan of hot water. When the nurse thinks the saline should be warm, the whole quantity is pumped with a two-bulb syringe into a vein at the elbow. An hour is allowed to pass, so that the patient may be warmed and the saline solution may take effect. He is then lifted onto a stretcher, carried to a chilly operating room, placed almost naked on a cold table, chloroformed, his wounds widely opened—to prevent gas gangrene—and the bleeding vessels tied. Returned to his bed, a friendly nurse puts several pillows under his head and shoulders, and his body sinks comfortably down on the springs, so that his feet and legs are also higher than the abdomen. He is surrounded with hot bottles and often receives a stimulating hypodermic. After this, he takes his chances.

This is a typical case and it explains perfectly why so many men die from low blood pressure.

## II.

My observations upon low blood pressures are set forth in a brief statement drawn up at the request of Professor Richet and presented by him to the French Academy of Sciences, October 30, 1916. This statement is as follows:

The number of wounded who suffer from low arterial pressure is very large, much larger than most surgeons believe. The greater part of these wounded can be saved.

I have studied low arterial pressures in my laboratory and at the front.

My observations upon animals show that: (1.) When the diastolic pressure remains some time at from 45 to 50 mm., it will not recover without aid. Unless the proper remedies are employed, the animal dies of shock. A diastolic pressure of 50 mm. is therefore "critical." (2.) When the diastolic pressure falls to 50 mm., the blood accumulates in the abdomen. This is a fact of the first importance. The animal bleeds to death in his own portal veins.

My observations upon wounded men at the front demonstrate: (1) That there is no essential difference between the low blood pressure of man and that of other animals. (2) The remedies that are successful against low blood pressure in animals are also successful against low blood pressure in human beings.

These remedies are: (1) gravitation; (2) the raising of the blood pressure by the injection of normal saline solution; (3) the raising of the blood pressure by adrenalin.

On coming from the ambulance, the wounded with low blood pressure should be placed immediately upon a special operation table (Fig. 1) heated by electricity. When an operation becomes necessary, the table is rolled into the operating room. The feet of the patient must be kept 30 cm. higher than the head, so that the abdomen may be higher than the heart and

\* Personal communication from Professor Richet.

Fig. 1.

brain. The patient must stay upon the table until the diastolic pressure will remain almost or quite at the normal level.

The treatment by the inclined position requires time—an hour or more. If the patient's state is grave, he might die before gravitation produces its effect. In such a case, it is necessary to raise the diastolic pressure immediately from 20 to 30 mm. above the critical point.

If, therefore, the diastolic pressure is less than 80 mm., normal saline solution should be injected into a vein. The injection should be slowly made, and it should stop when the diastolic pressure reaches 80 mm. If the pressure falls again, adrenalin should be injected into a vein, preferably near the malleolus. The object of these injections is to keep the pressure above the danger point until gravitation is able to maintain the pressure at a safe level.

Occasionally there are cases too low for immediate operation and in whom death is threatened from slight but persistent hemorrhage. Normal saline injections or adrenalin would increase the hemorrhage by increasing the blood pressure. Such cases demand the transfusion of blood. Some of the blood transfused will be lost by the hemorrhage, but enough may be retained to bring the patient to the point at which the vessels may be tied and the usual treatment for shock instituted. Since donors object to arterial transfusion, because of the operation and the fear, arrangements should be made for withdrawing the donor's blood from a vein into paraffined tubes.

Finally, there are perforating wounds of the chest, in which the inclined position threatens asphyxia, while if the patient sits up, he may die of shock. For such cases, there is no present remedy.

The application of the general principles just stated to the routine work of a military hospital demands more detailed instructions. At the close of the work at La Panne, my report to Dr. De Page on the systematic treatment of low blood pressures was issued by him to the staff (Note No. xxviii, *Sur le traitement du shock chirurgical*, Sept. 11, 1916), and it may serve here as an example of the necessary instructions. I quote only those parts of Note xxviii which may complete the data given above.

From a practical standpoint, shock exists when the diastolic pressure is 60 mm. or less. The blood then accumulates in the portal veins, the activity of the heart is impaired, and the nutrition of the nerve cells is affected. The treatment of shock requires:

1. A special position of the wounded; the abdominal vessels should be higher than the heart and the brain.
2. Heat.
3. Intravenous injections of normal saline solution.
4. Intravenous injections of adrenalin.
5. The transfusion of blood, in certain cases.
6. The taking of the diastolic pressure every half hour.

1. *Position:* The patient should be placed at once on the special bed,\* to be found in the Receiving Ward. This bed is of the following description: (a) the central part is of a size identical with a surgical operating table. (b) The removable side pieces increase the width to that of the ordinary hospital bed. The patient must not be taken from this bed as long as the arterial pressure is too low. (c) The foot of the bed must be raised 30 cm. The pillow must not be more than 6 cm. high. (d) The bed is heated electrically from below. (e) When the side pieces are lifted off, the bed is transformed into an operating table. (f) A stand 1.5 metres above the patient supports a bottle of normal saline solution, kept at 39° C. by an electric heater.

2. *Heat:* The heat should be continued until the feet and hands of the patient are warm. The heat should then be turned off at least for a time.

3. *Injections.* (a) When the diastolic pressure is below 80 mm., normal saline solution† should be injected into a vein. The fluid must be at 38° C. when it enters the vein. About 500 cc. may be injected, but it is not desirable to continue the injection after the diastolic pressure has reached 80 mm. The injection should be slowly made, lasting about 10 minutes. If the pressure falls some time after the first injection is given, a second injection‡ of normal saline should be made. The quantity should

\* This bed was described at La Panne (Sept. 11, 1916).

† At La Panne, 0.9 per cent. was used. It is called NaCl 0.9, but 0.85 NaCl 0.9 is given in the report.

‡ It is recommended by Professor N. O. R. that the second injection contain 1 gram adrenalin. I prefer to use 1 cc. of 100 mg. adrenalin solution.

again be 500 cc. provided a diastolic pressure of 80 mm. is not reached with less, and the injection should occupy about 10 minutes. (c) If the pressure falls below 80 mm. after the second injection, adrenalin should be injected into another vein. The adrenalin, in a solution of 1:1000, should be kept in a stoppered flask in the dark. Solutions not colorless should be rejected. At the moment of injection, mix 0.5 cc. of the adrenalin solution in 50 cc. of normal saline solution, at 38°. The injection should be made very slowly, and should be suspended if the heart becomes irregular.

4. *The transfusion of blood.* The indications for transfusion have been mentioned above.

5. *Measurements of the blood pressure.* The diastolic arterial pressure must be recorded at least every half hour. It is especially upon the diastolic pressure that the nutrition of the nerve cells depends. Since the heart-beat in low blood pressures becomes frequent and feeble, the systolic pressure is relatively more affected than the diastolic, and is therefore a less reliable guide.

I can myself bear witness that at La Panne the practical results of these procedures were most gratifying. Dr. Carrel tells me that the method has been found very valuable at Compiegne.

In every serious wound, it is most important that the diastolic pressure should be recorded at the earliest moment. With the auscultatory method, I have often made this measurement in two minutes. The longer a low arterial pressure continues, the more difficult the recovery. Yet very desperate cases may be saved. At La Panne, men who looked like a cadaver, and were almost pulseless, came back to life, and after two hours talked pleasantly of their children.

## FAILING CARDIAC COMPENSATION DURING PREGNANCY.

By CHARLES H. LAWRENCE, M.D., BOSTON.

Assistant in Medicine, Harvard Medical School; Assistant Visiting Physician, Robert Bent Brigham Hospital, Boston.

It is not the purpose of this paper to discuss the general subject of heart disease and pregnancy, nor to raise the question of the advisability of patients with cardiac disease becoming pregnant. So much has already been written upon these topics that there is now a definite basis for agreement, or disagreement, among obstetricians and internists concerning the influence of one condition upon the other.

Most of the data, however, have been collected in large lying-in clinics, and apply more correctly to the class of patients attending such clinics than to those met in private practice.

Moreover, the evidence is largely concerned with the mortality statistics of women with heart disease who become pregnant, and presents but meagre description of the factors which were potent in causing the results thus tabulated.

Face to face with the question of advising an individual not to have children on account of her cardiac condition, or that pregnancy be terminated before the period of viability for the same reason, statistics furnish a sound basis for general statements, but are disappointing as an aid to definite decision in any given case. Each problem is an individual one, and save in the very slight or very marked cases of cardiac disease, statistics are of value only in so far as the physician is able to place the patient in the proper classification afforded by tabulated evidence, and then correctly to judge the given heart as able or unable to meet the demands of pregnancy and labor. The risk lies in our ability so to judge. For though, as Stengel and Stanton have shown, pregnancy does not cause cardiac hypertrophy, and only a moderate dilatation of the right ventricle during the latter months, it *may* be the indirect cause of a greatly increased demand upon the heart through its common effects such as distention and insomnia, through its complications such as pyelitis or toxæmia, or through its termination by prolonged or difficult delivery. Therefore in estimating the ability of any heart to meet the possible demands of pregnancy, the margin of safety demanded must be a wide one and the estimation of cardiac compensation and reserve must be based upon thorough and painstaking examination of the circulatory apparatus, and upon the understanding that the patient must be very closely watched during pregnancy and labor for signs of failing compensation.

The classical signs of failing heart, dyspnoea, edema, and tachycardia, often appear too late to be of use in avoiding catastrophe, or give no warning of the acute dilatation which cuts short what is apparently normal life for the patient. Therefore, if patients with cardiac lesions are to be carried through pregnancy successfully, we must learn to recognize, and make use of, the minor signs of failing compensation.

What are these signs, and are they of any value in detecting diminishing efficiency of the circulation? Various attempts have been made to establish a simple functional test for the heart, but none has been completely successful. The evidence obtained by combining several is, however, valuable. All have the common characteristics of throwing some light upon the condition of the myocardium.

First among the methods of estimating the ability of the heart to meet the demands imposed upon it belongs the examination of the past history. It furnishes first, data concerning the amount of strain the heart has been, and therefore probably will be, called upon to meet by reason of the patient's habits and disposition.

In it may lie the explanation of failing compensation in a heart apparently only slightly damaged. And second, the history furnishes reliable information as to the heart's ability to respond, not to test exercises of measured amount, but to the total demand made upon it by life as the patient lives it.

In the absence of a history of a definite break in compensation, what points in the story suggest that the heart's efficiency has been seriously impaired? Careful questioning will often bring out the fact that the patient has had intermittent and transitory periods of feeling below par—especially characterized by disinclination to exercise. Not infrequently such periods are accompanied by slight, continued unproductive cough, and by rather poor sleep, for which no definite cause can be found. And occasionally there may be a story of an intermittent discomfort under the shoulder blade, or especially if the lesion be mitral stenosis, of slight pain in the praeordial area.

Such attacks are usually ascribed by the patient to any cause save the heart. But anyone who has the constant care of cardiac patients learns that the debility, insomnia and discomfort in chest or shoulder disappear under the influence of digitalis and rest, and are, in effect, signs of slight cardiac failure, and that a patient with such a history should not be subject to suddenly increased work, such as labor demands.

Whatever the physical examination reveals, such a patient, if she is to continue her pregnancy, should be placed under close observation, preferably in a hospital, in order that further tests of cardiac efficiency may be accurately carried out. The pulse rate under conditions of absolute rest and the change from it to moderate exercise should be carefully observed for several days. Taszkai states in a recent article that while normally the pulse rate increases with the change from lying to standing, this reaction is abolished early in pregnancy, and its reappearance means myocardial insufficiency. If further work supports this observation it will be a most valuable aid, but at present it can be said that a marked variation in pulse rate under conditions of rest and activity is a sign of diminished cardiac reserve.

Similar in principle is the observation of Schoonmaker of Philadelphia. He observed the variations in systolic and diastolic blood pressure in relation to posture and very moderate exercise. He concludes that with good myocardial efficiency the change from the lying to the standing position is accompanied by an increase in systolic pressure and a stationary or increased pulse pressure. Moderate exercise produces the same effect. A decrease in systolic pressure, together with a decrease in pulse pressure, has, in his experience, been associated with poor to bad myocardial efficiency. The writer has applied this test to a small series of cases,

and so far agrees with Schoonmaker as to its reliability in the non-pregnant. Whether it holds good during pregnancy, or, like the pulse variation, is abolished by that condition, remains to be proved. The point is worth investigating.

During the period of observation the patient's respiration should also be closely watched. The majority of lesions encountered during the child-bearing period involve the mitral valve, and cause increased strain, particularly on the right side of the heart. Beginning cardiac failure, therefore, means less efficient pulmonary circulation, with decreased oxygenation of the blood and tissues. This condition stimulates the respiratory center, and brings about an increase in the respiration rate. And observation of cardiac patients with slightly impaired compensation shows that the respiration rate averages higher than normal, and is more easily accelerated.

Another observation to be carried out is that of urinary output. This is of value, however, only when combined with a careful account of fluid intake, and without it may be exceedingly misleading.

In all cases of mitral stenosis, no matter how perfect the apparent compensation, the apex rate should be recorded with the radial, since a discrepancy between the two, or pulse deficit, gives valuable information concerning cardiac efficiency. The deficit appears earlier in stenosis of the mitral valve than in other conditions, and may be overlooked unless searched for as a routine. While it is true that some patients with mitral stenosis carry a constant pulse deficit, that fact is no argument against the condition meaning incomplete compensation. And analysis of cases shows that it is just those patients that are most apt to die suddenly and without other warning symptoms.

Recently, interest in the venous blood pressure has greatly increased with the production of clinical methods of recording it. From a prognostic point of view the work of Clark is most interesting. In the cases observed by him, a venous pressure over 20 centimeters of water is of bad prognostic import, as is a steady rise. He has further observed that urinary output bears an inverse relation to venous pressure. His observations need confirmation on larger series of cases, but if correct, will add one more sign to the list spelling early cardiac failure.

It is the writer's belief that a patient with cardiac disease who has exhibited the signs enumerated above to a degree sufficient to warrant a careful routine examination, should, while under observation, be given one further test—the therapeutic test of the effect of digitalis. The patient is anticipating an event which must throw suddenly greatly increased demand upon the heart. During the latter months of pregnancy there is a constant though moderate dilatation of the right side of the

heart. In the majority of cases it is the right side that suffers most from the lesion encountered. It is therefore fair to assume that at some stage of the game digitalis will be indicated, and if it can be ascertained beforehand, without harm to the patient, what the effect of digitalis will be, how much that particular heart requires, and how the required dose will be borne, the physician is in possession of valuable information. It is of course not necessary to give digitalis to every pregnant cardiac patient, but the writer believes it is a measure of safety to test the effect of small doses on any who have had signs of decompensation, even though the signs were not in themselves marked enough to demand its use in a non-pregnant patient. Under careful observation, the test is in no way dangerous.

Given a patient who has had slight failure of compensation which disappears under proper treatment, what shall be done during the remainder of pregnancy? First, the decision must be made at this point as to whether the patient may be allowed to continue pregnant, or whether the uterus must be emptied. And if the latter course be decided upon, it should be carried out at once. The physician should be in possession of enough evidence at this time to make his decision sufficiently certain to act upon, for if he hesitates further, he is likely to encounter conditions which make waiting and interference alike extremely hazardous.

If the patient has had a previous break in compensation or numerous small periods of sub-efficiency of the circulation, or if with mitral stenosis the latter only have occurred frequently, it is the writer's belief that pregnancy should be allowed to continue for one reason only—that the patient, in full knowledge of the risk she runs, refuses to forego the chance of bearing a child. Under such conditions, sudden death or chronic invalidism are too often the result of allowing pregnancy to continue to justify the physician in advising it.

If the patient elects to run the risk, what can be done in the way of treatment? Education in sparing herself all the strain she possibly can will do much. Some writers believe that too much emphasis should not be laid on the patient's condition, arguing that in such cases optimism is a great asset. With the latter idea the writer thoroughly agrees, but optimism should be based upon the patient's ability and willingness to give herself every chance and not upon the hope that she may pull through somehow. "It is a condition that confronts us, not a theory."

Should such a patient be given digitalis more or less continually? The writer's experience with ambulatory heart cases convinces him she should. Although digitalis is said to be indicated only in broken cardiac compensation, there are in every out-patient medical clinic numerous patients whose compensation remains

sufficient only so long as they take digitalis, and fails when they cease to do so. Its continued use does not provoke tolerance. There are on record at the Massachusetts General Hospital patients who have taken it practically continually for five years without harm or decreased effect. If in the latter months of pregnancy the right side of the heart is continuously dilated, and if the patient has superimposed on that condition a mitral lesion, digitalis logically should be of benefit. It is not necessary to give it daily, for, owing to its prolonged action, the patient may be kept under its influence by taking it, for example, five days a week during three weeks a month. Such a régime will often make the patient much more comfortable and will diminish rather than increase the work the heart does. Furthermore, it tends to prevent the accumulation of fluid in the abdomen and pelvic organs. The absence of demonstrable edema on the surface is not proof that it does not exist in the internal organs, to complicate operation and increase danger of infection if pregnancy be terminated, as it often is in such cases, by Caesarian section.

The other alternative is that which would be chosen for the non-pregnant patient—rest in bed so long as compensation cannot be maintained without the aid of drugs. Pregnancy, and impending labor, however, introduce the certainty that this rest cannot be continued indefinitely, and may be suddenly terminated by the extraordinary demand of labor upon the heart. In preparing for this demand, it seems more logical and actually gives better results, if the patient's general muscular tone, and particularly that of her cardiac muscle, be given the benefit of a moderate exercise, even though this régime requires the administration of some digitalis. Eliminating all exercise tends to produce muscular weakness and constipation, and is not the logical way to prepare the heart for the extreme effort of labor. That this is true practically as well as theoretically is shown by the results in such cases. Too often the heart, compensated for rest, is entirely unable to meet the demands of labor, even though that event be made as short and easy as possible. The writer believes, therefore, that it is wiser to treat the patient as an ambulatory case, guarding against decompensation by giving digitalis as described above, so long as the drug does not upset the stomach.

This latter condition cannot be too carefully guarded against. Abdominal or even gastric distention has more than once been sufficient to change the condition of the heart from good to fair, or from fair to poor compensation. The elimination of carbohydrates, and the division of the necessary amount of food into six small meals, often adds greatly to the comfort of a patient with slight cardiac inefficiency.

If digitalis is given, as suggested, any emergency arising during the period of its omission

can be met by intravenous medication—a method which should be used more often in cardiac emergencies.

In mitral lesions these emergencies are usually due to acute dilatation, mainly of the right side of the heart. Such a condition demands vigorous treatment, directed along two lines—first, the reduction of the load the right side is carrying, and second, stimulation of the heart muscle. To meet the first indication, venesection is by far the most satisfactory manoeuvre at our command. The writer has used it in twenty cases, has repeated it several times in several patients, and on the basis of this experience believes that it acts more promptly, more surely and more thoroughly than any medication. The amount of blood removed can be accurately controlled, and the bleeding stopped instantly if necessary. In emergency it can be performed in less time than it takes to give a hypodermic injection.

In obstetrics the objection may be raised against it that the patient, if labor ensues promptly, will lose still more blood, and that it is therefore unwise to deprive her of any beforehand. Venesection, however, may make all the difference between life and death. The amount of blood it is necessary to withdraw materially to benefit the heart is usually not over ten or twelve ounces. And with transfusion reduced to its present simple technic an equal amount of blood may be quickly introduced into the circulation. Venesection should not be withheld in the presence of acute cardiac dilatation from the fear of subsequent loss of blood.

For the stimulation of the myocardium *digitalatum* intravenously, or if the patient is free from digitalis, *strophanthin* intravenously have given the best results in the writer's hands. The latter has caused no bad effects when given to patients not under the influence of digitalis.

In spite of the greatest care in deciding which patients can go through pregnancy handicapped by cardiac disease, and in regulating their lives with regard to that handicap, there will be unavoidable catastrophes. Pregnancy and imperfect cardiac compensation are incompatible, and their coexistence constitutes always a grave menace to the patient. One or the other must be eliminated; either good compensation must be maintainable under ambulatory conditions, or pregnancy must be terminated. And if the patient's life is to be saved, the decision must be reached before the latter method of meeting the situation becomes too hazardous.

MISSISSIPPI VALLEY MEDICAL JOURNAL.—It is announced that the name of the *Louisville Monthly Journal of Medicine and Surgery* has been changed to the *Mississippi Valley Medical Journal*, which will be published as the official organ of the Mississippi Valley Medical Association, and will contain all its proceedings.

## SOME OF THE CLINICAL EVIDENCE RELATING TO THE ETIOLOGY OF EPILEPSY, INCLUDING SOME NOTES ON THE CONDITION OF THE TEETH AS A FACTOR IN ITS PRODUCTION, AND ON ITS RELATION TO ALCOHOLISM AND TO MENTAL DEFECT.

By HALE POWERS, M.D., BROOKLINE, MASS.,

*Second Assistant Visiting Physician for Diseases of the Nervous System, Boston City Hospital.*

STUDENTS of epilepsy will for some time be divided into a group who adhere to the tradition that it is primarily or entirely a disease of the brain, and a group who look upon it as an intoxication, probably of intestinal origin. The writer, although having for four years held the latter theory, has not yet been convinced that epilepsy is in every case the result of infection by a specific organism, because he has so often seen the arrest of the disease follow the correction of errors in diet and the relief of indigestion and constipation without any treatment designed to remove a supposed infection. On the other hand, he has never seen the arrest of the disease occur when those simple measures have been neglected, even after the removal of the colon, not to mention the persistent use of intestinal antiseptics.

In an article on the treatment of epilepsy by diet, published in 1914, the writer said that the outcome of a case might depend upon the repairing of the teeth. This statement might well have been more elaborated at the time, and in order to show on what basis of fact it rests, I have made notes on the condition of the teeth in fifty consecutive cases. In these cases the teeth have been classified as "good," "fairly good," "bad," and "very bad." In so classifying them, certain cases have been used as standards but it is admitted that those who know much about the teeth might draw the lines elsewhere. For example, a case in which two molars are absent and the other teeth are intact is classified as having fairly good teeth, by which is meant about the average; while one in whom one bicuspid is absent and two molars and two bicuspids are almost gone is classified as having bad teeth. One in whom four molars are absent marks the line beyond which cases are classified as having very bad teeth. Only the fitness of the teeth to perform the function of chewing has been considered, and the presence of unerupted teeth has not been sought for, because the object of the work has been merely to show that the failure of the teeth to perform their function is a factor in the production of epilepsy. In age the patients range from three and a half to sixty years. They have not been selected, and include almost all the conditions that have been supposed to produce epilepsy, with the probable exception of intracranial tu-

mor. In fully half of the cases the diagnosis of epilepsy was made before they were seen by the writer, and in none of the cases has the diagnosis been disputed by others.

Of the fifty cases, five have good teeth, five have fairly good teeth, thirteen have bad teeth, and twenty-seven have very bad teeth. Twelve of the patients when seen were subject to tooth-ache, some of them always finding it painful to chew. All of the fifty were constipated. Twenty-five readily admitted that they were bolters and eleven that they habitually ate too much. Three had severe gingivitis. At least one had chronic appendicitis, the diagnosis being confirmed by x-ray. One had syphilis. Six were feeble-minded and one insane. One of the feeble-minded has a cerebellar hypoplasia and one has spastic paralysis. The patient with spastic paralysis is the only one of the fifty in whom there is physical evidence that the brain has ever suffered trauma. This patient is an idiot, nine years of age. She is said to have been well and normal until one and a half years of age, the age when children begin to eat solid food. She then had diarrhea and a convulsion. After the first convulsion she had many others and many falls, and for a time she was in status epilepticus, during which time she is said to have been blind, and since which time there has been spastic paralysis of one arm and both legs. Briefly, when the child began to take solid food, she had diarrhea and then a series of convulsions, during which there was a cerebral hemorrhage. The digestive troubles and the convulsions have continued. She eats a great deal when permitted, and cannot chew because the upper molar teeth are carious and the upper front teeth are absent. She is very constipated. She has improved greatly since having her diet adjusted to the condition of her teeth. In this case, where there is imbecility and a cerebral palsy, digestive troubles preceded the epilepsy, and the epilepsy has become less severe under treatment of the digestive troubles. This has been true of all cases seen by the writer. This case is not an exception, but is typical of at least the majority of cases in which the diagnosis of "organic" as distinguished from "idiopathic" epilepsy has been made. The diagnosis of "organic" epilepsy is too often made merely because there is a history of a fall or an injury to the head. Overfeeding, in a mistaken effort to restore the patient's strength, is often the actual cause of an epilepsy following an injury or an illness. The following are three of a number of cases that I have seen which demonstrate this:

A little girl, six and a half years of age, was struck by an automobile. She was unconscious about half an hour and vomited three times. Five teeth were knocked out and there was much swelling about the face and head. About two years afterwards she had a grand mal attack and six months later another. Now, at the age of nine, she

is having one every two or three months. Neurological examination is entirely negative. The following facts, obtained on further questioning the mother, show how grave an error would have been made in calling this a case of "organic" epilepsy, even granting that there may have been a slight concussion of the brain. The child had to be fed through a tube for a time after the accident. She lost weight and the mother had tried to build her up. She thought home-made bread was a good thing for this purpose, and made it especially for the child, who was very fond of it, and also of beans (these being two of the articles of diet which are most certain to induce attacks in epileptics). The child is "a very hearty eater, but does not seem to gain flesh." The mother has tried to persuade the child to chew her food, but without success. The child is very restless, cannot sit still, and tosses and grinds her teeth at night. Sometimes the bowels do not move for two days.

Last winter a girl ten years of age, and otherwise well, was discovered by the school physician to have a heart murmur, and was advised to rest and have "plenty of nourishing food." Forced feeding was begun, and she ate four eggs daily for about six months. She became fat and constipated and then began to have petit mal attacks.

Three years ago a boy of seventeen had pneumonia. He had always been a bolter and a gourmand, and during his convalescence he was encouraged to eat still more, especially of milk and eggs. For three years he had several eggs and a quart of milk daily. Grand mal attacks began soon after the illness and have continued. Neurological examination is negative.

Not to study these cases from the broad, although commonplace, standpoint of the general practitioner is to be guilty of negligence. It is this failure to descend to the plane of commonsense that has made the treatment of epilepsy so unsuccessful. The statement so often made, that constipation and indigestion are the results of epilepsy, is not true. In more than three hundred consecutive cases the writer has invariably obtained a history of digestive troubles preceding the epilepsy.

Of the ten cases classified as having good or fairly good teeth, all are constipated. All have gross errors of diet. Seven admit that they are bolters and three that they are gourmands. Two have very bad home conditions and four are feeble-minded. The two with bad home conditions are a boy of fifteen who, because his father is a drunkard, is always compelled to go out and earn money to buy food before he can eat, and another boy of five who is neglected for the same reason. Epilepsy in the children of alcoholics is more rationally and more scientifically accounted for in this way than by heredity. It is desirable to emphasize this point because a great deal of labor has been expended in compiling statistics to show that epilepsy in the children is the direct result of alcoholism in the parents. It is not. It is the direct result of neglect and not of heredity. There is experimental proof of this in the fact that epilepsy in

the children of alcoholic parents is just as amenable to treatment as epilepsy in other children, provided that they can receive proper food and care.

The relation of epilepsy to mental defect is another subject in regard to which the writer believes the authorities to be in error. Its frequency in the feeble-minded has been regarded as evidence that it is a disease of the brain, but, as the writer has shown in a previous article on Diet in Epilepsy, the theory that it is an intoxication of intestinal origin is in absolute harmony with observations on the feeble-minded, and in fact it is here that some of the most convincing evidence may be found. All of the imbecile epileptics seen by the writer have swallowed their food without chewing, and have eaten more than they could digest, and some of them have had the habit of swallowing paper, wood, stones, buttons and other objects. This is the reason why the prognosis is bad in such cases. Mental defect developing after the beginning of epilepsy is another thing, and it may be accounted for in one or in all of three ways: by vascular lesions in the brain occurring during the attacks; by the destructive effect of irritating toxins upon the finer tissues and structures of the central nervous system, and by the similar effect of bromides. The first thing is known to occur, while the second and third are only reasonable hypotheses. In the children of mentally defective mothers, epilepsy occurs for the same reason that it occurs in the children of alcoholics, that is, because such children are not properly fed. Since January 1, 1914, thirty-four feeble-minded epileptic children have been examined, and there was not one without severe digestive troubles and the history of bolting and gourmandizing was given by nearly all the mothers. Some of the mothers said they allowed the children to eat almost constantly because it was the only way to keep them quiet. One of the evidences of mental defect which may be seen very early in life, and which I believe to be of some diagnostic value, is the absence of the sense of having eaten enough. It is akin to the blunting of other senses, sometimes seen in imbeciles.

Errors in diet seem to have been present in all of several hundred cases studied by the writer. By an improper diet I mean one containing an excess of fried food, fried meat, fresh white bread, and other indigestible things. Epileptic children are frequently made worse by drinking large quantities of milk. Any solid food that the patient will not or cannot chew should be forbidden. Notwithstanding statements in the text books, meat is not harmful to these patients if they will chew it. I have seen many a patient who has steadily grown worse on a vegetarian diet, improve on being allowed to eat meat, on condition that he chew it. The condition of the teeth is an important guide to be followed in prescribing the diet in epilepsy, which must be mechanically as well as chemi-

cally suitable for the patient. The theory that there is a deficiency of calcium in the tissues of epileptics seems to me to be inconsistent with the fact that my own cases have always done as well, if not better, with sodium bicarbonate treatment as with calcium lactate. The temporary relief that sometimes follows the exclusion of salt from the diet may be explained by the fact that the patient has eaten less because his food has been rendered unpalatable.<sup>2</sup> Recent investigators of heredity as a factor have found that it is of less importance than it was formerly considered to be, but whatever the frequency of heredity, it must not be forgotten that wrong habits of eating are handed down from one generation to another.<sup>3</sup>

As has been stated, twenty-seven of the fifty cases have very bad teeth. Of these cases fifteen have lost four, five, or six molar teeth; five have lost all molars; in five all upper or all lower teeth are absent or carious; in two all teeth are absent or carious; in one patient all teeth are artificial; and in one, half of the teeth are artificial. It is true that neglected teeth are seen more often in hospital than in private practice, and time has not permitted me to make notes on the condition of the teeth in fifty non-epileptic hospital patients for comparison with the fifty epileptics, but I have for comparison some data from my own records of the medical inspection of school children. In one of the Brookline schools I found, among two hundred and forty-eight children, only sixteen, or 6%, with bad teeth, according to the classification used in this work, while in this group of epileptics, 80% have bad teeth. We may conclude that epilepsy is not common in those who have good teeth.

Among my cases there are some in whom epilepsy began very soon after the loss of a number of teeth. Here are two such cases:

P. M., male, age 9.

*Family History.* Mother has had five pregnancies and has miscarried twice.

*Past History.* Birth difficult. Mother in labor three days. Instrumental delivery. Asphyxia. Weighed nine pounds. Breast fed. Did not hold head up for one year. Crept at two years. Walked with support at three years. Spoke at four years. Entered school at seven and is in Grade 3. Always promoted. Lost lower molar teeth between age of four and five. When permanent teeth appeared they soon decayed. Used to drool.

*Present Illness.* At the age of five he began to have attacks in which he was unconscious for a few minutes, and would clench his fists and set his jaws. Knows when attacks are coming, and calls for mother to bring water. No other history. Does not bite tongue, froth at mouth, or pass urine or feces. Frequency, about once a month, sometimes with an interval of several months. Has a good appetite. Eats more rapidly than other children. His mother says, "He wants to put in a great big bite and swallow it down."

*Physical Examination.* Heart negative. Some tenderness over cecum. All lower molar teeth ab-

sent. Eyes negative. All cranial nerves normal. No tremor. All tendon reflexes lively and equal. Cutaneous reflexes normal. No ataxia. Gait awkward with feet apart. Movements of hands awkward. Lower lip hangs down and mouth is open, while nares are not obstructed. Expression not alert. Eyes vacant. Does not pass mental tests suitable to age and environment.

In this case there was probably trauma at birth, causing mental defect, but the epilepsy did not begin until the age of five, and it followed the loss of the molar teeth.

A young woman of twenty was operated on for appendicitis three years ago, and after the operation she suffered from constipation. All her upper molar teeth and upper incisors were artificial and supported by bridge work. A year ago, because of severe trifacial neuralgia the artificial teeth were removed, so that she could no longer chew her food. The neuralgia was not relieved, and soon after losing the teeth she had an epileptic attack, and she has had three other attacks since then.

The work of having the teeth of these patients repaired proceeds very slowly, but at some future time I hope to report the results, if any, thus obtained. At this time it can only be said that those patients who have had the work done are doing well.

When there is difficulty in making a diagnosis between epilepsy and hysteria, or between epilepsy and intracranial tumor, a bad condition of the teeth, in which the chewing surface is inadequate, is evidence in favor of epilepsy.

Epilepsy is rare in breast-fed infants, and it does not often occur before the age of eighteen months. In another series of fifty epileptic children under twelve years of age, the writer found that in only seven it began before the age of one year, while in twenty it began between the ages of one and two, and in only twenty-three did it begin during the long period from two until twelve. Therefore, epilepsy in childhood usually begins at the time when the child is beginning to eat solid food that requires chewing, and when the teeth are often not sufficiently developed to do the work. In four of this series of epileptic children there was spastic paralysis, demonstrating injury to the brain, but the four were all feeble-minded, and gave the usual history of gourmandizing and bolting of food, which the writer believes accounts for epilepsy in the feeble-minded.

Epilepsy resembles tuberculosis in having no specific cure, and it should be treated, like tuberculosis, by common-sense methods, with close attention to detail. It has to be regarded at once from the viewpoint of the neurologist and from that of the general practitioner. Three years ago the writer suggested intestinal surgery in some cases of epilepsy, but he has seldom been compelled to advise surgery, because good results can be obtained without it, and in the majority of cases the dentist, rather than the surgeon, should be consulted.<sup>4</sup> The prognosis in

many cases of epilepsy depends largely upon the possibility of repairing the teeth.

The series of fifty cases is, of course, too small to prove that eighty per cent. of all epileptics have bad teeth, but if in a larger series the percentage were to differ by twenty-five with the percentage in my series, it would still show the majority of epileptics to have bad teeth. Most of my patients have been children, and in a series of adults the percentage having bad teeth would probably be higher.

The series of over 300 cases, in every one of which digestive disturbances preceded the epilepsy is, I believe, large enough to answer conclusively the question of whether the visceral changes found in epileptics at autopsy are primary or secondary.<sup>5</sup>

I am indebted to Drs. J. J. Thomas and A. W. Fairbanks for the use of the material in the Children's Hospital, where about one-third of the cases were seen.

### Clinical Department.

#### A CASE OF EPIDURAL INTRASPINAL ABSCESS OF PYOGENIC ORIGIN.

By W. J. MIXTER, M.D., BOSTON.

THE following case is reported in full on account of its rarity and also on account of my belief that there must be a few such cases, which, were they recognized and drained in time, would result favorably. It is a companion case to one reported herewith by Drs. Ayer and Viets.

Patient seen with Dr. J. W. Shaw of Newburyport, following a consultation with Dr. F. T. Lord of Boston, who advised exploratory laminectomy.

*F. H.*—Male, 17 years of age. *Family history* unimportant.

*Past History* negative except for furunculosis of face, which has been present to a greater or less extent since adolescence, and which has been quite severe during the past few weeks.

*Present Illness.* Sixteen days ago began to have pain in the left shoulder and about the left side of the chest, level of the fifth rib, increased on respiration. Also complained of sore throat. Was at home from school for a few days but did not see

his doctor. Improved enough to go back to school, but was still uncomfortable and evidently not in good health. Five days ago he was first seen by Dr. Shaw, as he had suddenly developed acute retention of urine. He was catheterized that day and examination of the urine was negative. There was no evidence of stricture or other obstruction. The next day he developed stiffness and weakness of both legs, headache, and stiff neck. The retention persisted. This was rapidly followed by a spastic paraplegia with temperature of 101°, and he was taken to the Anna Jaques Hospital. Lumbar puncture gave clear fluid not under excessive pressure with 2 cells per cc. Since then temperature has risen steadily and the paralysis has become complete in the legs. Seen by Dr. Lord last night.

*Examination* shows temperature 105, pulse 118, respiration 24, blood pressure 120, white count 30,000. Marked furunculosis of face. Throat somewhat reddened. General physical examination otherwise negative.

*Neurological Examination.* Conscious. Slightly confused mentally. Pupils equal and react normally. No choked disc. Other cranial nerves normal to hurried examination. Head held turned somewhat to the left. Neck stiff; rest of spine shows normal flexibility. No kyphos made out. Definite ataxia of hands (finger to finger and finger to nose). No motor or sensory paralysis of arms or hands. Arm reflexes not increased. Definite zone of hyperaesthesia from 7-9 D; complete anaesthesia below that level. Legs paralyzed, priapism, and retention of urine. Skin reflexes: abdominal not obtained. Cremasteric equal and normal on two sides. Normal plantar on left, Babinski on right. Tendon reflexes; knee and Achilles jerks not obtained. Kernig absent.

Lumbar puncture gave clear fluid with very faint yellow tint, not under pressure, which showed a definite coagulum on standing. Proteids greatly increased by ammonium sulphate and alcohol precipitation. Rare cell.

No x-ray was taken.

**Operation.** Laminectomy 3d to 6th dorsal inclusive. Beneath the epidural fat and outside the dura was found an abscess cavity cylindrical in shape running from the 3d cervical to the first lumbar vertebra and containing a large amount of creamy, greenish yellow pus under considerable tension. No evident focus of infection could be made out. The abscess cavity was drained with rubber and the wound closed rapidly. The patient died a few hours later. No autopsy was allowed. The pus showed a pure culture of staphylococcus aureus.

*Discussion.* A few words will suffice. By careful consideration of symptoms and signs it was evident that we were here dealing with transverse myelitis from an acute process; a pyogenic abscess was thought most likely, but the absence of knowledge of previous cases made us wary of exact diagnosis. The abscess found is to be considered, in my opinion, metastatic from the furunculosis or from tonsillar infection which was present in this case, in the same way that staphylococcus infection occasionally is found in perinephritic fat. The possibility of extension from an osteomyelitis of the vertebra must be considered, but the operative findings

make me feel that this was not the case; unfortunately, autopsy proof of this is lacking.

While extra-dural abscess formation of this type is rare, its importance is considerable, in that operation undertaken early should give in favorable cases relief from paralysis and bring about a cure. Certainly, the outlook should be considerably brighter than in cases where the abscess is secondary to infection of the spine.

Text-books on neurology and surgery are practically silent on this subject. Even in Elsberg's recent work, we fail to find mention of this type. It is for this reason that this case and the accompanying case of Ayer and Viets are here reported.

# INTRASPINAL EPIDURAL ABSCESS (PYOGENIC): CASE WITH AUTOPSY.

BY JAMES B. AYER, M.D., AND HENRY R. VIGGS, M.D.  
BOSTON.

[From the Departments of Neurology and Neuropathology, Harvard Medical School.]

THE two cases of epidural abscess of pyogenic origin here reported are worthy of consideration, not only because of the rarity of the condition, but because points of real diagnostic and therapeutic value are involved. True, both of these patients died, but there is nothing in either case which proclaims an unnecessarily bad prognosis for others of similar nature. Such a happy outcome was indeed obtained in one case reported by Raymond and Sicard.<sup>1</sup>

An exhaustive study of the literature has not been attempted, but a moderately thorough reading yields few references to the subject at hand. In Lewandowsky's *Handbuch*, where if anywhere one would look for light, references were found to but three cases falling into the group of epidural pyogenic abscesses, nor have we been able to fare better elsewhere. It should be here stated for clearness that from this group we exclude all cases of abscess primary in vertebrae or spinal cord; the condition here dealt with is this: *pus collection inside of spinal canal, but outside of the dura; its origin being metastatic or by direct extension; the organism pyogenic and not tubercular.*

Without further comment we will present our

Diagram to show course of infection from deep breast abscess by intercostal lymphatic to lymph node; thence by direct extension to back muscles and epidural space.

had difficulty moving his legs, and by September 29 he was paraplegic, with urinary and fecal incontinence. Neurological examination showed, besides the almost complete paralysis of legs, a mild bilateral sensory disturbance below umbilicus; k.j. present, a.j. not obtained, plantars normal, abdominal and cremasteric reflexes absent. Head and arms not remarkable. Examination of the back showed some fullness only in dorsal region and crackling rales at bases of lungs. Lumbar puncture gave 4 cc. only of clear yellow fluid, under no excess of pressure; the fluid clotting almost immediately. In twelve hours the fluid separated spontaneously from the clot and was found to give a negative Wassermann, a gold sol in the "meningitis" zone, great excess of proteids, and to be sterile on culture; the clot was macerated, and examined for cells, one only being found.

In seven days the patient died.

*Abstract of Autopsy.* Five hours post mortem.

Just to the right and below right nipple is an area, 10 cm. in diameter, of granulation tissue; from it no pus can be expressed, nor is there any in the surrounding tissue. The first incision into the back, however, yields a thick greenish pus; investigating deeper and more extensively shows that this pus has infiltrated the trapezius, latissimus dorsi and erector spinae groups of muscles. Dissecting to the spinal column, pus is seen to well up between the vertebrae, and when the laminae and spines have been removed, a thick coating of pus hides the dura from view for a distance of 10 cm., corresponding to the fifth, sixth and seventh dorsal vertebrae. The pus is easily stripped from its position on dura and from the nerve roots which it surrounds, leaving the former perfectly normal in appearance. The dura opened reveals a glistening inner surface and a cord of normal appearance, but the spinal fluid in the lumbar sac is of yellow color and, as analysis shows, is similar to that withdrawn previously. Even on section the cord presents everywhere normal appearance and markings.

Turning now to the pleural cavities: both con-

tain a small amount of sero-fibrinous fluid and a few fibrinous adhesions, especially posteriorly on the right. On cutting through the pleura at this region pus exudes, and search shows that it comes from two sources, the erector spinae muscles and necrotic paravertebral intercostal lymph glands, the latter being affected more particularly in the neighborhood of the fifth dorsal vertebra.

Other post-mortem findings are inconsequential. Abdominal cavity normal, but pericardial cavity contains slight excess of fluid. Intestines, pancreas, liver, kidneys, adrenals, heart and aorta all normal. Lungs show congestion only. Lymph glands of mediastinum, roots of lungs and mesentery all normal in size and appearance in contrast with the paravertebral glands above presented. A section of the fifth rib half way between axillary line and vertebral attachment shows medulla yellow-red, and no abnormality of the periosteum. Spleen large and soft. Cultures: pus from the back muscle; pericardial fluid and fluid from right pleural cavity—*staphylococcus albus* in pure culture. Heart's blood, no growth.

*Microscopic Examination* was carried out in routine manner on the tissues of the body, without striking addition to the gross findings. Microscopic examination of the spinal cord is, however, of considerable interest and importance, and is here given. First to be noted is that there is no distortion of the cord in the region of pressure and the size of the cord is not diminished; in fact, sections at one level suggest an actual, though slight, enlargement of the cord, fibers being separated more than normal, with presence of vacuoles, the cord at this point to the naked eye giving a moth-eaten appearance. While there is no certain destruction of nerve fibers, such degeneration is suggested by the presence of a few phagocytic cells in the rarefied areas of the white matter. Throughout the white also, but more particularly near the rim of the cord, a moderate increase in number and size of neuroglia cells is seen, some with faintly-staining protoplasm; no evident increase of glia fibrils is to be seen. The gray

matter presents normal configuration; the anterior horn cells are present in correct number, but many present the axonal reaction. Vessels appear normal and there is no evidence of dilatation or cellular infiltration of perivascular spaces. The pia is of particular interest because of its proximity to the abscess, which is separated from it only by dura. The pia shows a slight cellular infiltration, and on close examination the cells are found to be largely fibroblasts with a few plasma cells and lymphocytes; no polynuclear leucocytes are seen in the pia. Nerve roots, both dorsal and ventral, show perhaps a slight increase in fibroblasts, but no evidence of exudative cells.

#### DISCUSSION.

As clearly as ever falls to our lot, we are here enabled to follow the sequence of events from August 20, the date of the original infection, to death on October 6, which for clearness may be summarized: infection of skin of breast by a nail, leading to deep abscess formation; extension by intercostal lymphatics, chiefly fifth, to intercostal paravertebral lymph nodes, with destruction of the fifth, and subsequently one or two more, while at the same time the *point of infection heals*; infection then proceeds by continuity, at first causing a sero-fibrinous pleuritis, not leading, however, as would be expected, to lung abscess, but proceeding backward into the deep muscles of the back; thence upward and downward in these, and also inward between vertebral spines and intervertebral foramina until sufficient pus had accumulated over dura mater to cause pressure on spinal cord and symptoms of "transverse myelitis." The organism concerned is staphylococcus albus. (The accompanying diagram gives, in graphic form, the route of infection.)

Knowing the case as we do now, could surgery have helped? It is unlikely that anything could have been attempted until September 26, when the patient first complained of his back, the first indication that these back muscles had become infiltrated; the second warning, and one which the writers would now consider of great importance, is the onset of cord symptoms of the nature of a transverse myelitis, but especially the accompanying findings in the spinal fluid, namely, the "*syndrome de coagulation masive et de xanthochromie*." Such findings in the spinal fluid are, in the belief of many,—Froin<sup>3</sup> who described the fluid in 1903, of Raven,<sup>4</sup> Nonne,<sup>5</sup> of Mestrezat,<sup>6</sup> and others,—almost pathognomonic of pressure on spinal cord; the authors<sup>7</sup> have themselves recently reported a series of such cases, and are in hearty agreement as to its significance. It is not unlikely that even at this time surgery could have benefited if generous laminectomy had been performed.

Turning to another aspect of the case, it is interesting to note the efficiency of the barrier to infection presented by the dura. Pus must have lain on the dura under considerable pressure, if we may judge from symptoms produced and its configuration at autopsy, for at least

nine days, and yet no infection of the cerebro-spinal axis had taken place, as proved by negative culture, taken during life, and absence of cells characteristic of acute inflammation at autopsy. We know that the lymph stream is outward from the spinal canal, and yet it is astounding that under pressure this direction should not be reversed in all this time. Even more striking in this regard was the case of E. A. Oppenheim,<sup>8</sup> who reports a case of similar nature in which pus had pressed upon the dura for 25 days without subdural infection! The changes within the cord are interesting; though no true infection of the cord has taken place, there is already evidence that a breaking up of the cord is under way, as evidenced by the phagocytic cells found in this substance, by the axonal reaction of the anterior horn cells, and by the proliferation of neuroglia suggestive of attempt at repair.

We wish to express our thanks to Dr. Nathaniel S. Hunting of Quincy and Dr. Walter E. Paul for clinical data in connection with this case.

## Medical Progress.

### REPORT ON OBSTETRICS.

By ROBERT L. DE NORMANDIE, M.D., F.A.C.S., BOSTON.

#### ABDOMINAL PREGNANCY.

SOLOMONS<sup>1</sup> reports a case of abdominal pregnancy which occurred in his practice, with a brief review of the causes and treatment. He defines abdominal pregnancy as a development and growth of the fetus in the abdominal cavity, which may be either primary or secondary. He regards a primary abdominal pregnancy as unlikely, and thinks that secondary abdominal pregnancy is more credible.

He regards the diagnosis of abdominal pregnancy as extraordinarily difficult, making note of the fact that various men have tapped the abdomen, thinking that these cases of abdominal pregnancy were ovarian cysts. The diagnosis of this condition may be established by the following points: the extreme sensitiveness to palpation; there are no intermittent contractions; the irregularity of the outline of the

tumor; the fetus is directly under the skin, and the heart sounds are directly under the ear; a further point is that retroversion is a common accompaniment of this condition.

He records the history of a patient, a woman of thirty-three, married ten years, who never became pregnant until the present instance. Her last menstruation was early in July, and she was admitted to the hospital on December 31. Four months before admission to the hospital she had pain in the abdomen, which gradually increased until it became unbearable. She suffered from dysuria. Examination of the abdomen showed a mobile tumor, dull on percussion, fairly regular in outline, extending to the umbilicus. Bimanual examination showed the cervix to be retroverted. The tumor in the abdomen seemed connected with the cervix, yet there was a soft, cystic swelling in the front and lateral fornices, and this was also connected with the abdominal tumor and cervix. Fetal parts and movements were distinguishable, both abdominally and by the vagina. Solomons said he could not make a definite diagnosis, and he determined to open the abdomen. He opened the abdomen and found a tumor, hemorrhagic in appearance, stretching a little beyond the umbilicus. Separating the adhesions between the tumor and the intestines in the omentum, a finger entered the amniotic sac and a fetal foot appeared. There was much hemorrhage, which was stopped by oversewing. He removed the fetus and placenta, and with it the right tube. The uterus, left tube and both ovaries were left *in situ*. He found the uterus lying retroverted, practically imbedded in the tumor which filled the pelvis. The patient was in poor condition, and he closed the abdomen as quickly as possible. The abdominal wound healed by first intention, and she was discharged from the hospital in good health on the twenty-sixth day.

Solomons makes a few remarks on the treatment of abdominal pregnancy from the time when the condition was first found post mortem, next until treatment was postponed until after the death of the child, then when the child was removed and the placenta was left. There is a review of the literature, and from his own case he feels that the rational treatment is to remove the fetus and placenta and to stop the hemorrhage, and that it is bad policy to leave the placenta *in situ*.

There is a short bibliography at the end of the article.

#### THE APPLICATION OF ANOCI-ASSOCIATION TO OBSTETRICS.

Hoag<sup>2</sup> has been studying a number of cases where the anoci-association principles were applied in obstetrics, combining with the principle, nitrous oxide and oxygen, chloroform and ether, or chloroform alone with the anoci-association. Combined with some of his cases he used scopolamine. In all cases the perineum was injected

with a 0.25% novocaine, in varying amounts from 50-160 cc. Eleven patients he gave in addition 30-40 cc. of 1% quinine-urea solution. The maximum amount of the two solutions injected in any one case was 175 cc. An injection was made as the head appeared in sight. The vulvar edges were turned back, and a long needle was inserted at the muco-cutaneous border. Novocaine was injected first and the quinine-urea immediately afterwards. By this technique, he says, the levator-ani and the perineal body can be readily infiltrated. He tabulates his cases under three groups: first, those that received nitrous oxide, scopolamine and perineal injections; second, those that had nitrous oxide and chloroform or ether with scopolamine and perineal injections; third, those that had chloroform only for delivery, no scopolamine, but had perineal injections.

He concludes that nitrous oxide analgesia is safe to both mother and child, and the use of limited amounts of scopolamine during the first stage is a distinct advantage, shortening the time during which gas is required, and making the analgesia more complete. He believes that the injection of the perineum is a distinct help in securing relaxation of the outlet, and he feels that there is no complication whatsoever resulting from the perineal injections. The combined use of scopolamine, nitrous oxide oxygen and local infiltration offers a practical and efficient means of conducting labor, and extends "anociation," in its broadest sense, to the obstetrical field.

#### PERINEAL ANALGESIA IN LABOR.

King<sup>3</sup> reports his experiments at perineal analgesia in a very interesting illustrated article. His technique is as follows: First, he uses 2% solution of novocaine, sterilized by boiling. To this solution he adds one-third of a minim of 1:1000 solution of adrenalin chloride to each em. He then palpates the pubic arch to be sure of the landmarks where the injection should take place, and this he clearly shows in the diagrams. The anterior injection is made 2-4 cm. below the vagina and 2 cm. from the rami of the pubis. The needle is passed 2-4 cm. in depth, corresponding to the level of the hymen. The expression of sudden pain as the needle meets the positive resistance of Colles' fascia, indicates the proper depth. The posterior injection is midway between the anus and the tuberosity, with the needle inclined, and injection takes place at about 4 cm. The injections are made bilaterally. Primiparae, he states, require only anterior injection, while multiparae require both anterior and posterior injections.

He summarizes his paper by saying that in nearly one hundred injections no adverse results have followed. Analgesia begins in a few minutes, and is prolonged two to four hours. Lacerations are diminished in number and ex-

tent, for the consciousness, without pain, of the patient, allows retardation or advancement of the presenting part at will, thereby developing the fullest elasticity possible. Hemorrhage is greatly diminished, due to adrenalin and lessened extent of tears. The repair of the tears is greatly facilitated because of the anesthesia, and when the posterior triangle is infiltrated, all the obstetric area can be rapidly and painlessly sterilized by iodine under this preparation. He finally states that the general practitioner can safely and easily apply the method at the bedside.

#### A STATISTICAL STUDY OF 635 LABORS WITH THE OCCIPUT POSTERIOR.

After a very thorough analysis of 635 labors where the occiput was posterior, Plass<sup>4</sup> comes to the following conclusions:

1. The frequency of occiput obliquely and directly posterior positions was 11.57% in the series (7500 cases).
2. Rotation of the occiput into the hollow of the sacrum occurred in 14%.
3. Three factors which tend to favor rotation into the hollow of the sacrum are, poor flexion, small size of the head, and funnel pelvis. Contractions of the pelvic inlet favors anterior rotation.
4. The etiology of internal rotation is not satisfactory; but Hodge's theory of the ischial spines and inclined planes is most acceptable.
5. Premature rupture of the membranes was not especially frequent when the occiput was posterior.
6. Spontaneous delivery was the usual outcome. The total operation incidence was 22.9%, but in only 11.02% was the position possibly accountable for the need for intervention.
7. There was no increased infant mortality because of the posterior position.
8. Labor was not prolonged, independently of whether the occiput rotated to the symphysis or in the hollow of the sacrum.
9. A contracted pelvis did not increase the incidence of the posterior positions.
10. There was no additional maternal morbidity or mortality.

#### CARE OF THE PERINEUM.

Plass,<sup>5</sup> in order to determine whether routine antiseptic treatment of the perineum after delivery had any beneficial effect upon the course of the puerperium or upon the healing of primary perineal repairs, carried out the following clinical experiment:

All patients delivered from November, 1911, to August, 1915, were divided alternately into two groups, A and B. Group A were given the routine perineal care with antiseptics. Group B were given no special attention. The routine perineal care consisted in bathing the vulva and perineum with cotton pledgets soaked in 1:2000

bichloride of mercury solution every four hours, as well as after each defecation and urination for the nine days the patient remained in bed. In Group B the patients were merely kept macroscopically clean with warm tap water and soap and a wash cloth. Unless the patient was very ill, she was expected to clean herself. In this group Plass found the average number of cleansings necessary were four a day for the first three days; from the third to the sixth day not more than two a day, and after this only one.

The results obtained by the two methods Plass tabulates in two tables, and from these tables he concludes that the routine care was followed by many poor results, whereas excellent results were obtained by the new method, and, therefore, the use of antiseptic solutions in the care of the perineum is of no value; macroscopic cleanliness alone giving better results. In addition, he says that much economy in the time of the nurses is obtained.

#### POST-MORTEM CESAREAN SECTION: A REPORT OF TEN CASES.

Harrar<sup>6</sup> reviews the early cases of post-mortem Cesarean section reported, noting that in 107 reported cases no living child was extracted. In 1914 Hallman reported 68 cases, with 61.68% of living children. Harrar advises against post-mortem version or forceps, unless the death of the mother occurred during the second stage of labor.

Harrar advises the physician to secure the consent of the husband or the family if instantly at hand, but he says if consent is not obtained and the fetal heart is still going, it is not only permissible, but imperative, for the physician to do all he can to save the child. Bacon has shown that Cesarean section is legal without consent, and must be done if the child is viable and alive.

The ten cases which Harrar reports occurred, are from the clinic of the Lying-in Hospital. Of these ten cases, three babies were still-born. Four babies were born with hearts feebly beating, but with no attempts at respiration. One baby gave a few feeble gasps and died. One baby, slightly asphyxiated at birth, died on the sixth day of pneumonia. One baby, badly asphyxiated at birth, left the hospital living and well, and one cried at delivery and was discharged well.

#### DOES ADMINISTRATION OF PITUITRIN TO THE MOTHER PRODUCE DIFUSE STROKES IN THE INFANT?

Heard<sup>7</sup> raises the question, whether the administration of pituitrin to the mother can cause nervous lesions in the infant. He reports three cases in full where the infants shortly after birth showed evidences of extensive cerebral injury, due, Heard thinks, undoubtedly to the birth. These three cases were not first born.

in no case was there any constitutional disease on the part of either of the parents or of the children; in no case was there any question of a prolonged or difficult labor; in each case a precipitate delivery was effected by pituitrin.

Heard concludes: (1) that the improper use of pituitary extract in labor is a cause of cerebral or meningeal hemorrhage in the newborn; (2) that hemorrhages in the nervous system of the infant, resulting from the use of pituitrin in labor are productive of diffuse nervous lesions so extensive as to result in early death, or if the child survives, in the terrible afflictions of paralysis, epilepsy and idiocy; (3) that cases presenting nervous lesions resulting from birth injuries should be carefully investigated as to the possibility of pituitrin having been a factor in the causation.

#### RUPTURE OF THE SCAR OF A PREVIOUS CESAREAN SECTION.

Findley's<sup>8</sup> article on rupture of the scar of a previous Cesarean section is based on his review of the literature of the subject, out of which he has found sixty-three cases of rupture of the scar. He says that when he began his review he had prejudice in favor of repeated sections, but as the work developed he concluded that such a position was untenable.

The greatest factor in the production of insecure wound healing is septic infection. He admits that there is no positive assurance of obtaining a perfect wound healing, whatever the method of suturing or whoever the surgeon. The uterine scar is an unknown factor in all cases. The transverse fundal incision has given more than its share of ruptures, and as yet it is too early to state how well the scar in extra-peritoneal and cervical sections will stand repeated pregnancies and labors.

The sixty-three cases which he found are carefully tabulated and analyzed, and his conclusions are:

1. A perfectly healed Cesarean wound may be relied upon to resist the forces of labor, but in view of the fact that the integrity of the wound is an unknown factor in all cases, we are constrained to exercise the utmost caution in the conduct of every case in pregnancy and labor following Cesarean section.

2. Failure to secure perfect healing of the uterine wound is because of departure from the principles of suture proposed by Sanger, or because of septic infection.

3. Latent gonorrheal infection may defeat the most painstaking effort.

4. When a Cesarean section has been followed by a fever course, the uterine wound should be regarded as insecure, and should call for a repeated section at the onset of labor.

5. Sterilization and hysterectomy should replace conservative Cesarean section when infection is known to exist.

6. The possibility of rupture of the scar following Cesarean section does not justify sterilization. In subsequent pregnancies the labors should be hospital cases, and if the wound is known to be defective, then a repeated section should be done.

7. Version, high forceps, hydrostatic bags and pituitrin should never be used in the presence of a Cesarean scar.

8. There is evidence that not more than 2% of ruptures occur in subsequent labors, and that, therefore, we are not justified in voicing the slogan, "Once a Cesarean section, always a Cesarean section."

Findley finally adds, however, that the liability of rupture is real, and, therefore, this should stand as an argument against the increasing tendency to widen the scope of elective Cesareans.

A long bibliography follows this article.

#### MEDDLESOME MIDWIFERY IN RENAISSANCE.

From DeLee's<sup>9</sup> article one gathers that at the present time there is much meddlesome midwifery going on throughout the country. He feels that the average physician does not give to the cervix its proper importance, and that the serious tears that the cervix is subject to are a cause of much invalidism.

He feels that the notion which the public and the profession have entertained for many years, and which is becoming more prevalent among the profession of late, that natural labor should be curtailed as much as possible, is explained partly by the agitation in the lay press for the relief from suffering of childbirth. He says that methods to shorten the time of labor have been multiplied, and great virtues have been claimed for them. He says that, without doubt, protracted and painful labor does weaken the parturient, but that there are no permanent effects from this. The amount of surgical trauma determines the smoothness of recovery even more than the stress of the nerves. DeLee calls attention to some of the most common evils which have gained footholds in obstetrics. The first he notes is the attempt to cut short the period of dilatation of the cervix. Manual dilatation, he says, always tears the cervix. Colpeurynters often do, and almost invariably do, if traction is put on them. In addition, they pull the cervix downward, while the uterine action pulls it upward. The danger of infection attends all these manoeuvres, though he says it is true that women seldom die of sepsis, but the morbidity, immediate or postponed, is high. Another form of interference is the indiscriminate use of twilight sleep, gas and oxygen, and other anesthetics. DeLee says that he, himself, uses anesthetics too often and too liberally, and that this increased use of anesthetics has increased the number of forceps operations, lacerations and post-partum hemorrhage in his

own practice. He further warns the physicians against allowing the parturient to bear down before the cervix is fully dilated, for by this the cervix is dislocated and much damage follows. He warns against too frequent vaginal examination and the "ironing out of the perineum." He favors the use of rectal examinations, and states that with little practice great efficiency can be obtained. He regards the giving of pituitary extract the most dangerous of all the meddling practices. He refers to sixteen cases of rupture of the uterus that are on record, and states that hardly a month goes by but that he learns of cases in which the baby has been lost after the use of pituitary extract. He demands that pituitary extract be used only in the presence of a really scientific indication.

He again repeats the charge that the abuse of obstetric forceps is real, and he deplores the fact that often the indication is "bed-time, office hours or some other set appointment." DeLee makes another interesting point, that Cesarean section is too frequently performed, commenting on the fact that in some communities it seems that the only method of solving difficult obstetric problems is to cut them.

#### PUERPERAL GANGRENE OF THE EXTREMITIES.

Stein,<sup>10</sup> in a very complete article in which he has given abstracts of all the cases that he can find up to the present time of puerperal gangrene of the extremities, reviews the etiology, symptoms, prognosis and treatment of this serious complications of the puerperium. He also reports two cases of his own. His first case was that of a woman who had a septic abortion at three months. The temperature varied for six days in the puerperium between 104 and 105°. Stein examined the patient on the seventh day, and he decided to curette her, as the uterus was still enlarged and soft. After the curettage, the interior of the uterus was swabbed with tincture of iodine, and this was repeated the next seven days. Even after the curettage, the temperature did not drop, but kept between 101 and 102°. Seven days after the curettage the patient began to complain of pain in the right leg, and three days later the right leg and foot began to swell, became cold and showed bluish discoloration. Pulsation in the dorsalis pedis artery was not felt, and the foot was extremely painful to the touch. The line of demarcation became marked, and three days later amputation was performed below the knee. The patient then recovered.

His second case was a patient delivered at term by forceps. Had a second degree laceration repaired with chromic catgut sutures. Two days after delivery patient had slight chill, with temperature of 104.5°. Temperature varied from 101 to 102°. Six days after the delivery, sutures were removed because the whole area was sloughing. Patient continued to run a temperature varying from 103 to 104°, and, in spite of her very serious condition she left the

hospital, against advice, twelve days after delivery. She was readmitted seven days later with a temperature varying between 102 and 104°. Examination revealed both feet symmetrically discolored for a distance of about four inches above the ankles, and were nearly black and the skin was shrivelled. Both feet were extremely tender on touch, and in some places showed vesicles filled with a whitish fluid. Even though the line of demarcation was well pronounced, the patient's condition did not permit of any operative interference, and she died on July 19, five weeks after the delivery. No autopsy was obtained.

Stein says that the arterial origin of peripheral puerperal gangrene is probably the most common, and is probably always due to infection. Thrombosis of the arteries of the leg might be due to an ascending thrombosis of the uterine artery. The smaller blood vessels sometimes become obliterated through embolic plugs, which often become detached from the thrombi in the large arteries. In favorable cases, onset of gangrene is prevented by the establishment of compensatory collateral circulation. Stein says it is not clear why, in certain cases, the septic process becomes localized in the internal wall of an artery, and in other cases in the venous wall, or in both. The most common cause of peripheral gangrene is known to be a septic endarteritis and embolism from diseased heart valves usually occurring in cases of grave puerperal pyæmia. Mechanical factors, recumbent position and relative immobility of the entire body may also enter into the cause. The majority of these gangrenes concern the lower extremities, although the upper extremities are occasionally involved. In regard to the symptoms, pain is very pronounced and never absent in extensive vascular obliterations such as lead to peripheral gangrene. The ordinary symptoms of puerperal fever are present in the majority of cases, and sudden onset usually points to embolism in the arterial system, while, on the other hand, the gangrene may develop very insidiously in the case of a small embolus. The absence of arterial pulsation below the thrombus is an important sign. The sensibility is usually distinctly diminished, while mobility may be preserved. A livid discoloration and a relatively diminished temperature of the affected area add to the probability of incipient gangrene. The prognosis of puerperal peripheral gangrene is governed by the time of the performance of amputation. Unfortunately, amputation is not always practicable on account of the patient's bad condition or because the seat of the obstruction is located high up in the aorta. One-half to two-thirds of the patients die. The treatment consists of purely conservative measures and the appearance of the line of demarcation is a signal for amputation. Prophylaxis is that of ordinary aseptic and antiseptic management of all deliveries.

## POSTURE IN OBSTETRICS.

In an illustrated article, Markoe<sup>11</sup> shows the development from ancient times of the so-called obstetric chair. He says in the development of the use of forceps the necessity of posture was gradually lost sight of, so that at the present time but little is said in its favor. Markoe feels that the first stage of labor should be observed more carefully than it has been in the past, and that obstetricians, both in the hospital and in private practice, should exert their efforts to make this stage as short as is compatible with perfect safety. He feels that posture is of great assistance, and it is because of his desire to make use of this procedure that he first revived the so-called obstetric chair. His method is as follows:

When regular contractions have been established, the patient is instructed to conserve her strength by not remaining too long in one position, but to sit from time to time in the chair, with the knees elevated so that they support the enlarged abdomen and to have the chair so padded with pillows and blankets that the maximum of comfort is offered. By thus sitting in a chair as he has depicted it—a rocking-chair can be used—the weight of the uterine contents is exerted on the cervix, not in a harmful way, but with a steady hydrostatic pressure that at this stage does more to shorten the labor than anything else. If the patient becomes restless in the chair, or the contractions are severe, she may with benefit walk about the room, or even recline. The inclination of the chair, he says, is of the greatest importance, for by changing this inclination the axis of the uterus may be made to point directly into the pelvis. Markoe says that since he has used the chair he has performed fewer operations, such as Cesarean section, versions and forceps, and that there is a decrease in the deaths of mothers, fewer stillbirths and fewer deaths of the child following labor. As far as perineal lacerations go, it has apparently made no difference with them. In his article there are various tables which show the length of time which the patients were kept in the chair, the various abnormal conditions met, and the results obtained.

## ACCIDENTAL HEMORRHAGE.

Wing<sup>12</sup> reports two cases of accidental hemorrhage upon which he did Cesarean section.

The first patient, a primipara 7½-8 months pregnant, twenty-two hours before admission to the hospital, fell heavily against the bathtub, striking her abdomen. Abdominal discomfort followed at once, and in three or four hours the patient was having severe abdominal pains, with cramp-like exacerbations. Ten hours after she fell she began to bleed by vagina.

When examined at the hospital she was nearly exsanguinated; slight bleeding from the vagina. Cervix barely admitted a finger, and no placenta was felt. The uterus was of the size corresponding to a pregnancy of eight months and

was tonically contracted, having the consistency almost of wool. No fetal heart heard.

Cesarean section was determined upon, and when the uterus was exposed it was found firm, somewhat distended, much deeper in color than normal and showing numerous petechial areas. The uterus was incised and the placenta found in the region of the fundus, almost entirely separated. The dead fetus, placenta, membranes and clotted blood were removed and the uterus closed. The uterine muscle seemed softer than usual and deeper in color, and it bled scarcely at all. Twenty-four hours after operation, the patient was transfused because of her poor condition. Improvement followed, and she was allowed to go home on the twenty-second day. Twenty days after leaving the hospital she returned with an attack of erythema nodosum, from which she recovered.

Wing's second case was also a primipara in about the eighth month of pregnancy. Fifteen hours before admission to the hospital she began to have slight labor pains. Seven hours before admission bleeding from vagina occurred. A physician who was called, packed the vagina with iodoform gauze, and referred her to the hospital some hours later.

On admission her general condition was good. Fetal heart, 140. The uterus was very firm, and remained more or less tonically contracted. Cervix thick and barely admitted a finger tip. No placenta felt. The uterus was tender. It was noted that the head, which was above the brim, moved laterally when the uterine contractions occurred, in the direction of the left iliac fossa. Wing, on watching this patient, explained this peculiar lateral movement of the child by some cord entanglement, and that the bleeding was due to a partial separation of the placenta. Wing decided upon a Cesarean section, and he found the cord twice around the neck, and its insertion in the placenta was almost marginal and at the lower border. The child was born alive and did well.

Wing's explanation of this accidental hemorrhage is that the short cord pulled off a portion of the placenta. A diagram of the condition found accompanies the report.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.50 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

FERNET GREGORY, Manager.

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

## INDUSTRIAL HEALTH INSURANCE.

THE subject of industrial health insurance, now interesting a considerable proportion of the medical and legislative community, is novel to most persons in this country, but is far from being a new social phenomenon. It was established in England before the outbreak of the European War; in Germany as early as 1883; and in Russia rudimentary attempts in the same direction were made in 1806 to protect the health welfare of industrial workers. The appearance of the problem, therefore, in our own community is to be looked upon as an inevitable evolutionary step. The compensation of working men for injuries received in the pursuit of their occupation has already been established in this country, though many of the details of its administration are not as yet satisfactorily adjusted; and experience has shown in other countries, that where once the policy of neglecting disease or leaving its care to private interests has been abandoned, a complete series of social health legislative measures has ultimately been

adopted. Viewed in the historical perspective, therefore, it appears now that the problem of industrial health insurance and other forms of medico-social legislation should be met by the medical profession in a spirit of friendly criticism, recognizing their intrinsic justice and desirability, and endeavoring to profit by the experiments of others in securing such conditions and details of administration as shall make such acts equitable and beneficial to all.

In last week's issue of the JOURNAL we published the text of the Dotten Bill, a measure of industrial health insurance introduced before the Massachusetts General Court at its latest session, and now under consideration by the recess legislative committee. Closely similar bills have been introduced into the legislatures of about twenty other states. In the same issue we published an expository editorial, aiming to point out in brief the leading propositions of this bill and their relation to the medical profession. This publication was in no sense intended as an endorsement of the Dotten Bill. While recognizing the desirable principle of industrial health insurance, we doubt that this bill, or any other bill hitherto drafted, would satisfactorily secure the benefits of this principle for the community. The present purpose of the JOURNAL is to foster and encourage frank and open discussion of the entire problem, and to this end it has planned to devote its issue of December 21 to a symposium of articles, dealing with various aspects of the subject from several points of view. In subsequent issues its columns will be freely opened as heretofore, to contributions and discussions, presenting different standpoints and opinions. The question is many-sided, and it is only by its temperate and careful discussion, in a spirit of amity and genuine interest for the common welfare, that the best solution can be profitably attained.

## SHOCK AND LOW BLOOD PRESSURE.

IN a remarkably graphic and lucid article, published in another column of this issue of the JOURNAL, Dr. W. T. Porter of Boston records the interesting results of his personal investigations last summer into the subject of shock, as observed at the front and in hospitals immediately behind the fighting line in Europe. His vivid narrative not merely presents accurately

the conditions under which he sought to determine the genesis of shock, but illustrates admirably the fact, not often made obvious in medical papers, of the romantic interest attaching to scientific research when its object has so direct a bearing on clinical medicine.

The outstanding fact resulting from Dr. Porter's observations in France, correlated with his previous experimental study of shock in laboratory animals, is that shock is essentially a vaso-motor phenomenon associated with a persistent lowering of the diastolic blood pressure to 50 millimeters or less. The possibility of recovery from shock is dependent upon the possibility of restoring this pressure to within normal limits. The patient suffering from this condition, unrelieved, dies essentially of splanchnic, or intra-portal, hemorrhage.

Dr. Porter points out not only these facts, and the causes by which the condition of shock is induced under the circumstances of warfare, but also the remedies by which it may be successfully combated. These are, briefly: posture, warmth, intravenous infusions of normal saline solution and of adrenalin, and blood transfusion. Individually, these methods have doubtless been known and practised by many surgeons. It seems hardly likely, however, that they have been consistently practised in sequence in the treatment of surgical shock as seen under the circumstances of civil practice, where, of course, the physiologic and pathologic phenomena of shock are the same as in warfare, though the etiology may differ. The two important facts of Dr. Porter's paper are its clear presentation of the genesis, nature and rationale of treatment of shock, and its exemplification of the possibilities of valuable service of scientific methods in elucidating the problems of clinical medicine and pointing out the way for their solution.

#### PROGRESS OF POLIOMYELITIS.

DURING the past week there has been a slight recrudescence of poliomyelitis in Massachusetts. One new case was reported on December 9, making a total of 18 cases during the first 9 days of the month. The numbers of cases during the preceding months in Massachusetts were: July, 107; August, 252; September, 623; October, 702; November, 179.

Report from St. Paul, Minn., on December 1, states that Dr. E. C. Rosenow, working at the Mayo Clinic with Dr. E. B. Towne of Boston, and Dr. G. W. Wheeler of New York, has isolated a polymorphous streptococcus from the tonsils and pharynxes of over fifty patients in the acute stage of poliomyelitis; and that with cultures of the larger forms of this organism, the disease was consistently reproduced in susceptible animals. The authors are reported as saying of these observations: "The exact relation of our results to the facts already established as to the etiology of poliomyelitis cannot yet be definitely stated. It appears to us that the small filtered organism which has been generally accepted as the cause of poliomyelitis, may be the form which this streptococcus tends to take under anaerobic conditions in the central nervous system and in suitable culture media, while the larger and more typically streptococic forms, which investigators have considered contaminations, may be the identical organism grown larger under suitable conditions."

Report from Washington, D.C., on December 2 states that a resolution has been drafted for immediate presentation to Congress, calling for an appropriation of \$250,000 to be expended by the United States Public Health Service on an intensive study of poliomyelitis. The weekly report of the Service for November 24 records a general decline of the disease throughout the United States. During the month of October the largest numbers of cases outside of Massachusetts were: 254 in New Jersey, 250 in Pennsylvania, 238 in New York exclusive of New York City, 148 in Minnesota, 143 in Illinois, 120 in Maryland and 84 in Wisconsin.

Apart from continued research into the etiology and transmission of the infection, the most important problem now connected with the epidemic of poliomyelitis is the after-care of convalescents from the disease. In previous issues of the JOURNAL we have noted the beginning already made in Boston in the special clinic established at the Children's Hospital. Similar work is being done at the Massachusetts General Hospital, and at other large clinical centers in the State. In New York, where exists the largest group of these patients demanding attention, the problem is in the hands of a committee on the after-care of infantile paralysis, which was organized as the result of a series of conferences, called by Dr. Haven Emerson. It

is not desirable that after patients are dismissed from quarantine, they should pass out of the jurisdiction of the health department. The following description of the organization and work of the committee is quoted from the weekly bulletin of the New York Health Department as a valuable outline of the method adopted in dealing with the after-care of poliomyelitis in that city:

"The committee has undertaken three main lines of work: first, to coordinate the work of the dispensaries and nursing agencies, so that no child should want or wait for treatment; second, to organize dispensary transportation for all the children who needed it; and, third, to raise funds to aid in the treatment, home care and training of these children.

"To accomplish the first of these, the committee divided the entire city among the following four home-visiting agencies: the Committee on Crippled Children of the Brooklyn Bureau of Charities, the Henry Street Settlement, the Association for the Aid of Crippled Children, and the Bureau of Educational Nursing of the New York Association for Improving the Condition of the Poor. To November 16, 5409 children had been referred to these agencies, and largely through their efforts 3288 of these were reported as being then under treatment, either with private physicians or in the dispensaries. In addition to these, 86 cases have been referred to the social service department of the New York Hospital, where the patients had been as acute cases; 85 of these are reported as having begun treatment. Among those reported as under treatment is a small number who have no residuary paralysis, but are being examined occasionally so that no deformity may unexpectedly develop. The visiting nursing agencies also do the dispensary social service work where it is not otherwise provided.

"While the city was easily divided among the nursing agencies, it has been difficult to divide it among the dispensaries. Many things had to be considered,—equipment, personnel, location, local need, transportation, preference of parents, etc. As a matter of fact, most of the patients are being cared for by about twenty dispensaries, while half of that number are doing most of the work. The committee is still trying to group the cases about the best dispensaries and into districts convenient for transportation.

"To accomplish the second of these purposes, the committee secured and operated a small number of ambulance busses and motors, on its own account and through the cooperation of the Sick Children's Transfer Society, the Social Service Department of Bellevue Hospital, the Forward Fund and the Militia of Mercy. The Board of Estimate and Apportionment has made a small appropriation to the Department of Charities to provide transportation to and

from the dispensaries, where necessary, and it is hoped that eventually the transportation will be fully provided by the city. In the mean time, the committee will continue its service and will doubtless find it necessary to supplement the city's transportation in special cases.

The agencies upon which the burden of after-care fell did not hesitate for lack of funds to begin work. But it was soon found that they must have additional funds. Either they must raise them through separate appeals, or the Committee on After-Care must raise money for them. While this question was pending, the Public Health Committee of the Academy of Medicine and the Associated Out-Patient Clinics recommended that the Committee on After-Care take this opportunity to promote the best standards of equipment and personnel in the dispensaries engaged in after-care. Accordingly, a budget was prepared, and a large citizens' finance committee was appointed to raise money for the treatment, home care and training of these children. The committee is asking for a quarter of a million dollars, which, however, will not care for them till they are recovered, but will carry the work into, if not through, the second year. None of this money will be used for the administrative work of the committee—this cost having been met by the Rockefeller Foundation—but will be used only for after-care, first of all through established needful and satisfactory agencies, and second, to encourage new ones where the children of a locality cannot be conveniently treated otherwise. At the request of the Commissioner of Health, the Committee on After-Care will administer the brace fund, raised by the Department of Health as a result of public appeals.

"The Committee on After-Care consists of a general committee, representing the Department of Health, the Department of Public Charities, the hospitals, dispensaries, nursing associations, and other welfare agencies; a Committee on Transportation, comprising more than a hundred names; a Medical Council of twenty-one orthopedists, neurologists and pediatricists; and a Finance Committee of two hundred men and women."

## HEALTH AND SANITATION IN THE NAVY.

THE recently published annual report of the secretary of the United States Navy records the work of that national department for the fiscal year ended June 30, 1916, but includes operations and recommendations to December 1 of this year. Particular attention is directed to the section of the report dealing with health and sanitation in the navy, to which an especial medical interest attaches. In this section it is

pointed out with how much care the personal health and welfare of young men in the navy is safeguarded. As a matter of fact, during the past year the death rate of the naval personnel was only 4.48 per thousand, whereas the death rate of men in the same age period, exposed to the ordinary hazards of civilian life, was 8 per thousand.

"Incident to the nature of a seafaring life is, of course, the constant menace of drowning, and of our total deaths, 51, or one-sixth, are due to this cause. Of these, however, 21 are those who went down with the *F-1*.

"It is noteworthy that the three predominant causes of death—drowning, tuberculosis, and pneumonia—all show, upon analysis, encouraging improvement over preceding years. Tuberculosis, also, as it is handled in the navy, is found less frequently in naval than civilian life. To quote statistics again, our civil population between the ages of 15 and 60 years owes 30% of its total deaths to this disease; naval mortality during 1915 owes 11% of its deaths to this cause, and this is being materially bettered each year.

"The activities of the medical department of the navy during the past year have been unusually marked. Naval and military developments of this unprecedented epoch of military history are constantly being observed, and proper use made thereof in the plans and activities of our own service. Our medical officers detailed for observation purposes with the warring powers are informing themselves of all facts available pertinent to the medico-military aspects of naval life."

After a brief discussion of the medical activities of the navy in Haiti and Santo Domingo during the past few years, the report emphasizes, as follows, the indispensable importance of the hospital ship and the nature of the personnel of enlistments in the navy:

"The usefulness of a hospital ship as a necessity in modern warfare has been emphasized by the European conflict; and the naval act of this year, besides increasing the Medical Corps from 347 officers and 1500 men to 600 officers and 3000 men, besides facilitating advancement in the Hospital Corps from the lowest enlisted rating to that of actual commissioned officer, and besides increasing the total appropriation for the medical department from \$682,000 last year to \$1,187,728 for the current year, has led the navies of the world in authorizing the construction of a model hospital ship, which will be a veritable *Bellerophon* afloat. The war across the Atlantic has demonstrated the value of the hospital ship. The British alone employed over 40 ships of this class during the Gallipoli cam-

paign. These ships and the ships employed by other nations, however, were designed for other purposes, and hastily converted to meet the emergency. The new hospital ship being constructed by the Philadelphia navy yard will be an oil-burner, with all that this means for comfort and cleanliness. A stabilizer will make for steadiness afloat. Not only will she provide hospital accommodations for the sick of the fleet, but experience of a number of years with the *Solace* has shown the necessity of making provision for an out-patient department, wherein men of the fleet may receive special treatments and examinations, returning to their ships on the same day.

"The navy is also to be congratulated upon the consistently maintained standards that are giving us a personnel which is the pick of the ambitious youth of our nation. During the past year 106,392 sought enlistment in the navy. Of these, only 30.18% were accepted. During the last four years, owing to a full or relatively full complement, the large number of applicants, and consequent ability to make more careful selection, the percentage of acceptances has decreased from an average for the previous six years of 52.67 to 30.18. The present rigidity of physical requirements not only insures a fine standard of men, but helps to lighten the pension load of the country in future years. The urgent need of more men, as would happen in time of war, could be met by a modification of the standards without entailing the acceptance of any deficient types."

Finally, the report describes the advances that have been made in the medical education of candidates for the navy hospital corps. In 1914 two training schools for hospital corps men were established,—one at Newport, R. I., and one at San Francisco. Successful schools have also been established at Samoa and Guam for training native women as nurses.

"Homes for nurses at Mare Island and Boston have been furnished, and provision has been made on the coast lines south of Norfolk and Mare Island, which are as yet unprovided with navy hospitals, for the calling into being of mobile Red Cross hospitals of 250 beds each, with complete personnel and equipment. To prepare the Medical Reserve Corps, a correspondence school has been initiated for the purpose of training these officers. The higher standards, the zeal and sacrifices of the men in this corps, and their devotion to health and sanitation, cannot be too highly commended.

"Authority has been given by Congress for ample reserve stock, medical and surgical supplies, which is recognized as essential in a comprehensive plan of being ready for emergencies."

### MASSACHUSETTS CONFERENCE ON FEEBLE-MINDEDNESS.

IN last week's issue of the JOURNAL we noted the annual conference of the Massachusetts Society for Mental Hygiene, which is being held during the present week at Ford Hall, Boston. The entire conference this year is devoted to the subject of feeble-mindedness, and an admirable program, of which a portion was published last week, has been arranged. At the initial meeting, on the evening of December 13, Dr. Walter E. Fernald, superintendent of the Massachusetts School for the Feeble-minded, at Waverley, discussed the present practicabilities in the way of protection, education, supervision and segregation of the feeble-minded, pointing out our present lack of adequate facilities for this purpose.

"Many feeble-minded persons eventually become permanent public charges. Many run the gamut of the police, the courts, the penal institutions, the almshouses, the tramp shelters, the lying-in hospitals, and often many private societies and agencies, perhaps, eventually, to turn up in the institutions for the feeble-minded. At any given time, it is a matter of chance as to what state or local or private organization or institution is being perplexed by the problem they present. They are shifted from one organization or institution to another as soon as possible. At present there is no bureau or officer with the knowledge and the authority to advise and compel proper care and protection for this numerous and dangerous class."

The afternoon meeting of Thursday, December 14, will be devoted to a discussion of the problems associated with feeble-mindedness and illegitimacy, and the evening session of that day to a symposium on types of delinquent careers, and feeble-mindedness regarded from its legal aspects and in reformatories. On Friday afternoon, December 15, will be discussed methods of caring for the different groups of feeble-minded subjects, and on Friday evening there will be a final meeting with papers, among which will be one by Dr. Robert M. Yerkes on the diagnosis of children needing special care, and one by Prof. William H. Burnham of Clark University on pseudo-feeble-mindedness.

The problems of feeble-mindedness, like many others of those with which the present generation has particularly undertaken to deal, are as yet far from complete or satisfactory solution. It is only by coöperative interest in conferences such as the present that ultimate progress may be expected.

### PETER BENT BRIGHAM HOSPITAL.

THE recently published second annual report of the Peter Bent Brigham Hospital covers the activities of that institution for the year ended Dec. 31, 1915. During this time there have been admitted into the wards of the hospital 3417 patients and there have been 8536 new patients treated in the out-door department. The x-ray department made 4572 examinations and there have been over 2229 examinations made in the serologic laboratory and 750 studies in the respiration laboratory. The total operating expenses for the year have been \$269,913.46 and the receipts from patients have amounted to \$88,651.55.

In the report issued by the Hospital of its first year's work, attention was drawn to the utter lack of uniformity in the statistical tables of surgical cases and operations as they are presented by the various hospitals of the country which make any pretense at all of tabulating the results of their surgical work. Unquestionably their value would be increased if the hospitals of a given community would agree upon a uniform system of tabulation. To this end the report of the surgical department contains the following statement of progress toward this result. "A committee on hospital organization had already been established by the Massachusetts Medical Society, and in conjunction with representatives of the major hospitals a meeting of this committee was held at which an agreement was reached and a sub-committee appointed. This sub-committee has held several meetings, and it is hoped that eventually some uniformity in nomenclature as well as in the system of tabulations may be agreed upon. The so-called 'International Classification,' though compiled merely for the purpose of registration of mortality statistics, has been utilized by many institutions, chiefly with the Bellevue modifications and rearrangements, as a means of recording morbidity statistics as well. Unsatisfactory as this classification is for clinical purposes, it has nevertheless seemed best to continue to build upon this foundation until some more acceptable method is devised, in the hope that more hospitals will near(ly) become accustomed to the use of the title numbers."

## MEDICAL NOTES.

**NEW YORK DIAGNOSTIC SOCIETY.**—Report from New York on November 30 announces the organization in that city, of the New York Diagnostic Society, consisting of about three hundred physicians and surgeons, with the following officers: Dr. M. Joseph Mandelbaum, president; Dr. Dewitt Stetton, first vice-president; Dr. Otto Hensel, second vice-president; Dr. Julius Auerbach, treasurer; Dr. Monroe Kunstler, secretary. This Society has already raised a fund of \$100,000 and when this sum is doubled it purposes to build, establish and maintain a diagnostic hospital, with a staff of experts by whom diagnoses will be made and patients referred either to a specialist or to the general practitioner by whom they were first sent to the Hospital.

**PREVALENCE OF DISEASE IN THE UNITED STATES.**—The weekly report of the United States Public Health Service for November 24, 1916, states that during the month of October there were eleven cases of cerebro-spinal meningitis in Massachusetts, forty-one of malaria in New Jersey, and three hundred and sixty-seven of typhoid fever in Maryland.

**CHOLERA IN TURKEY.**—It is reported that Asiatic cholera became epidemic in Turkey in June, 1916. From that time until the middle of September there were 9009 cases of the disease with 4651 deaths.

## EUROPEAN WAR NOTES.

**REPORT OF BELGIAN RELIEF FUND.**—The recently published third annual report of the New England Belgian Relief Fund contains the following statement by Mr. John S. Codman, manager of the local relief fund.

"Our fund was organized in October, 1914. The Belgians were the first war sufferers, and, as they had at the beginning the undivided sympathy of the New England public, the contributions came in very rapidly during the first three months of the fund's existence. Later, as was to be expected, after the first burst of enthusiasm and when the needs of other peoples began to claim attention, the contributions fell off despite the ever-increasing need.

"During the early months of the war there were also large contributions of food.

"In January, 1915, the cash receipts were swelled by a sale of a large consignment of potatoes contributed from Maine and sold for cash, and in February \$16,000 was received as the proceeds of the Belgian Kermesse. During the spring and summer of 1915 receipts were very small, but on Nov. 17, 1915, a second general appeal was sent out for funds to purchase clothing for the coming winter, and the receipts

for November jumped from \$2300 at the close of business on Nov. 17 to \$31,300 at the end of the month. In 1916, the spring again showed a falling off, but in the summer, as the result of persistent advertising, the receipts, compared with corresponding months of the previous year, were greatly increased with little additional expense. These receipts are not really attributable to those months, but should be spread over a number of months.

"In the autumn of 1915, a great effort was made to meet the urgent call for clothing needed for the winter in the conquered part of Belgium, and \$60,000 was spent for this purpose in the three months of October, November and December.

"The total purchases (mostly clothing) for the year Oct. 1, 1915, to Sept. 30, 1916, amounted to \$121,411.34.

"In addition to the above spent for relief in the conquered part of Belgium, \$10,000 was forwarded to the Rockefeller Foundation to help the work of removing children from the war zone in Flanders to Switzerland, there to be cared for and educated.

"The sales force has been utilized for much clerical work in connection with letter appeals for funds, and these appeals have brought in at headquarters over \$7000 cash contributions at a very small percentage of expense. Still other cash contributions, amounting to nearly \$9000, have been received at headquarters.

"The books of the fund have been audited by Harvey S. Chase & Co., covering all transactions up to May 1, 1916, and their report shows total contributions and interest on same \$366,211.72, total spent for relief \$332,433.87, and \$11,834.13 cash on hand, indicating a total administrative expense of \$21,943.72, or only six cents out of every dollar contributed.

"Through the kindness of Montgomery and Stone and other well-known theatrical stars, a very enjoyable performance was given for the benefit of our fund in the Colonial Theatre on Jan. 28, 1916.

"On April 26, 1916, a band concert was given for our fund in Symphony Hall by the Cercle Musical Instrumental of the Union Belge, Inc., Modeste Alloo conducting. The band was assisted by Mlle. Renée Longy, Mr. Georges Longy, Mr. De Maitly and Mr. Orphée Langevin.

"Our fund coöperated with other local relief organizations in the Massachusetts booth of the Allied Bazaar in New York last June. From this the net proceeds to our local Belgian fund amounted to approximately \$500, but as one-third of the net proceeds of the Allied Bazaar itself went to the Commission for Relief in Belgium, our efforts in behalf of Belgium are represented by a sum considerably larger."

An earnest appeal for continued support is made to the public by the executive committee of the Belgian Relief Fund.

**RED CROSS RELIEF IN SERBIA.**—Report from Washington on November 29, states that the Austro-Hungarian government has requested the American Red Cross to discontinue on December 1 its relief work in Belgrade and northern Serbia. As a matter of fact, this work had practically come to a standstill since the beginning of the Roumanian invasion, for the supplies distributed by the Red Cross in northern Serbia were largely procured from Roumania.

"Nearly \$75,000 has been contributed to that section from this country, while 100 carloads of supplies from Roumanian relief committees and eighty from Swiss committees have been distributed by the American agents. Edward Stuart, assisted by Charles Fox, has cared for about 36,000 people in Belgrade and Dr. Edward Ryan has endeavored to reach about 100,000 in the interior.

"American relief in southern Serbia now is thrown into greater importance by Austria's request and especially by the advance of the Allied armies about Monastir. Reports from that city say 200,000 people are in distress, as the retreating armies of the Central Powers are said to have stripped the city bare of food and supplies. Shipments are being prepared for that section."

**AMERICAN RED CROSS WAR RELIEF.**—In a recent letter from Miss Ethel W. Putney, Secretary of the American Red Cross Committee at Cairo, Egypt, which has, for some time past, been supplying food and clothing and affording medical attention to some 4,000 or more Armenian refugees living in a "tent city" on the outskirts of Port Said, Egypt, a request is made for \$16,000 for the continuance of this work during the next year. The Red Cross and the American Committee for Armenian and Syrian Relief have joined in providing the amount requested.

"Individual gifts," says Miss Putney, "have practically ceased. Therefore we come to you for the whole sum of our next year's budget. We shall greatly appreciate if you will cable us your decision at your earliest opportunity. You will readily see that our plans for the winter which is shortly upon us depend upon your granting this budget."

Among the refugees are 700 cases of pellagra, and in order to meet the special diet requirements of these patients, a considerable increase of expense is necessary. The Committee has established a system of hot baths in the camp, which is giving great satisfaction and is of material assistance in maintaining the health of the refugees.

The camp is largely self-sustaining through a system of industries which permits a great many of the inmates to be kept steadily employed on productive labor. For instance, about 200 women are making crochet work, while a great

many of the refugees are employed at manufacturing army shirts, of which about 1,000 are turned out every week. These are sold to the British Army at good prices.

Through its agents in Saloniki, the American Red Cross is preparing to undertake the relief of a large number of distressed civilians in southern Serbia, particularly in and about Monastir, just as soon as it is possible to enter that section behind the lines of the Serbian Army. The Red Cross agents have cabled an estimate that 200,000 civilians occupy the section of country just wrested from the Bulgarian forces by the Allied troops, and that a very large percentage of this population is in need of assistance. Because of rough roads and the lack of railway facilities the agents suggest that food supplies be sent in small cases which may be carried on pack trains. The Red Cross is also requested to send three two-ton trucks for the transportation of supplies.

A first shipment of food supplies, purchased at a cost of \$5,000, will leave New York within a day or two, and \$5,000 additional have been cabled to the agents at Saloniki for emergency purchases. As the situation develops, large additional shipments of supplies will follow and it is probable that the Red Cross staff in Saloniki will be increased.

**WAR RELIEF FUNDS.**—On Dec. 9 the totals of the principal New England relief funds for the European War reached the following amounts:

Belgian Fund .....	\$192,934.54
French Wounded Fund .....	163,516.81
Armenian Fund .....	128,721.98
French Orphanage Fund .....	71,241.31
British Imperial Fund .....	70,322.31
Polish Fund .....	52,371.26
Permanent Blind Fund .....	39,835.94
Italian Fund .....	28,233.04
LaFayette Fund .....	21,079.03
Wittenberg Prisoners' Fund ..	2,013.65

#### BOSTON AND NEW ENGLAND.

**WEEK'S DEATH RATE IN BOSTON.**—During the week ending Saturday noon, the number of deaths reported was 209, against 219 for the same period last year, with a rate of 14.33, against 17.35 last year. There were 28 deaths under one year of age, against 41 last year, and 64 deaths over 60 years of age, against 90 last year.

The number of cases of principal reportable diseases were: diphtheria, 36; scarlet fever, 20; measles, 8; whooping cough, 4; typhoid fever, 9; tuberculosis, 46.

Included in the above were 10 cases of cases of non-residents; diphtheria, 6; scarlet fever, 4; tuberculosis, 7; smallpox, 1.

Total deaths from these diseases were: diphtheria, 1; typhoid fever, 2; tuberculosis, 2.

Included in the above were the following deaths of non-residents: tuberculosis, 2.

HOSPITAL BEQUEST.—The will of the late Joseph Faulkner of Hamilton, Mass., which was recently filed for probate at Salem, Mass., contains a bequest of \$5000 to the Lynn Hospital, to be known as the Faulkner Fund, the income to be used for the general purposes of the Hospital.

### Massachusetts Medical Society.

#### WORKMEN'S SICKNESS INSURANCE AND THE DOCTOR.

WORKMEN'S SICKNESS INSURANCE, whether in the form of the Dotten bill or in other guise, is largely a medical question. If a bill providing for it should be passed without more care than was evidenced in the passage of the present Accident Compensation Law in this State, it seems probable not only that medical care of the injured workman would be poor, but that the whole practice of medicine in the Commonwealth would be disrupted; for the law seems likely to include in its provisions, families as well as actual wage-earners within a \$1200 limit.

Our profession has a record for altruism, but to ask us to sacrifice ourselves to a plan which we are not sure of as a benefit even to our patients would be absurd!

The undersigned—a committee appointed by the Council of the Massachusetts Medical Society, in June, 1916, to look after the interests of the profession in this matter—have given a good deal of study to the question, and have tried to profit by the work previously done by others. Also, we have kept in touch with the Recess Committee of the Legislature, designated to consider this among other questions for report to the coming legislative session.

It has seemed to us timely to present to the profession a draft of provisions that represent what we may call the irreducible minimum of medical rights. In the drafts for bills, and in the bills introduced for such legislation to date, the medical side has been strangely neglected.

We understand that the proponents of the Dotten Bill have now in preparation changes and amendments to meet this neglect. Nevertheless, though hoping that others may protect our interests or rights, we feel it the duty of medical men to protect themselves.

The draft herewith submitted is put before the medical profession of the State for consideration and discussion. It should not be given out as representing the opinion of the profession until we have more expression of opinion.

There seems to be some divergence of view in the profession as to the value of the main principle involved. This is natural. Your committee may well be wrong in this, but we have felt that it was not within our province to pass on this very large question; we have felt

that it was for us only to detail the conditions necessary, in case such a bill should pass the Legislature, in order that the workingman should be cared for, and cared for properly, without utterly ruining the doctor.

We believe, by the way, that ruining the doctor would often kill or spoil the workingman.

The draft herewith presented seems to us to represent the minimum demands we must make if the proposed legislation is to go through. More unfavorable conditions must result in inferior medical service, and so work to the defeat of the intent of such legislation.

The working man will necessarily hesitate in his adherence to a scheme that does not take proper care of him. The doctor is far within the edge of his rights, if he wants to know where he comes in.

**SECTION 1. Medical, Surgical and Nursing Attendance.** All necessary medical, surgical and nursing attendance and treatment shall be furnished by the carrier from the first day of sickness, during the continuance of sickness, but not to exceed twenty-six (26) weeks of disability in any consecutive twelve (12) months. In case the carrier is unable to furnish the benefit provided for in this section, it must pay the cost of such services actually rendered by competent persons at a rate approved by the Commission. Competent physicians and surgeons shall mean those upon the panel, as provided for in Section 2. By the rate approved by the Commission shall be meant the rate established in Section 4. By furnished (lines 3 and 6) shall be meant furnished as provided in Section 2.

**SECTION 2. Medical and Surgical Service.** On or before . . . . . every physician and surgeon who, being legally qualified to practise in Massachusetts, shall desire to serve under this act, shall register for this purpose with the Commission, and each carrier shall be, within a reasonable time after such date, furnished by the Commission with a list of physicians and surgeons so registered. From this panel, so constituted, the carriers may indicate to their insured a preference, but the patients shall have free choice among the physicians or surgeons upon this panel, subject to the physician's or surgeon's right to refuse service on grounds specified in regulations made under this act by the Commission, provided, however, that no physician or surgeon on the panel shall have on his list of insured patients more than 500 insured families or more than 2000 insured individuals. The Commission shall, upon presentation of satisfactory evidence that any physician or surgeon upon the panel is incompetent, neglectful of his duty, or dishonest, suspend or remove such physician or surgeon from the panel, and decision of the Commission shall be final.

**SECTION 3. Appointment of Physicians and**

*Surgeons as Referees.* The Commission shall establish Districts and shall appoint a physician or surgeon as referee in each District; such referee shall be paid by the Commission a salary not to be less than \$ per annum and shall devote his entire time to the work. It shall be the duty of such referee to supervise the character of the medical and surgical service in the interest of the insured patient, the physician, the carrier and the Commission. He shall decide all disputes involving medical or surgical questions that arise between insured patients and physicians, between physicians serving upon the panel, between insured patients and carriers, or carriers and physicians, including the termination of disability. His decision may be appealed from to the medical advisory board, whose recommendation shall be given to the Commission, whose findings shall be final.

*SECTION 4. Payment of Physicians and Surgeons.* Physicians and surgeons, serving upon the panel, shall be paid by the carriers for medical or surgical services rendered to the insured a fee per visit that shall be not less than the average minimum fee for services rendered by physicians and surgeons of the locality in similar cases. Services rendered in maternity cases shall include previous supervision, when applied for, for at least six (6) weeks previous to the delivery, and supervision for four (4) weeks after birth, included as a part of the care of childbirth.

In case of dispute between physicians and carriers as to charges for services, the Commission shall have the power to decide, and their decision shall be final.

*SECTION 5. Medical and Surgical Supplies.* Insured persons shall be supplied by the carrier with all necessary medicines, surgical supplies, dressings, eye glasses, trusses, crutches and similar appliances prescribed by the physician, not to exceed in cost for any one insured person the amount of \$ in any one year.

*SECTION 6. Hospital Treatment.* Hospital or sanatorium treatment and maintenance shall be furnished upon the approval of the medical officer of the carrier instead of all other benefits, except as provided for in Section , with the consent of the insured member or that of his family, when it is not practicable to obtain his consent. The carrier may demand that such treatment and maintenance be accepted when required by the contagious nature of the disease, or when in the opinion of its medical referee, such hospital treatment is imperative for the proper treatment of the disease or for the proper control of the patient. Cash benefit may be discontinued during refusal to submit to hospital treatment. Hospital treatment shall be furnished for the same period as cash benefit. This benefit may be provided in those hospitals and sanatoria with which the carriers have made

satisfactory financial arrangements, provided that such hospitals are of a standard approved by the medical advisory committee. A charge of \$15.00 per week shall be considered a proper charge per patient for hospitals and sanatoria.

*SECTION 7. Maternity Benefits.* Maternity benefits shall consist of all necessary medical, surgical and obstetric aid, materials and appliances which shall be given insured women and wives of insured men. A weekly maternity benefit payable to insured women equal to the regular sick benefit of the insured for a period of ten (10) weeks, of which at least six (6) shall be before delivery, shall be made on condition that the beneficiary abstain from gainful employment during the period of payment.

*SECTION 8.* From a list of twenty (20) physicians or surgeons recommended by the Massachusetts Medical Society and the Massachusetts Homeopathic Medical Society, each in proportion to its total membership, the Governor shall appoint a Medical Advisory Committee of five members to serve respectively five, four, three, two years and one year. Vacancies on this board from death or resignation shall be filled for the unexpired term. Each succeeding appointment, except for the filling of such vacancies, shall be for five years. The members of this Committee shall be paid only for actual expenses incurred in the performance of their duties. It shall be the duty of this Committee: (1) to advise the Commission on medical matters; (2) to standardize contracts with hospitals and dispensaries; (3) to hear and act on all disputes arising, including such as are referred to them on appeal as provided in Section 3. Their findings shall be transmitted to the Commission for approval and adoption.

It is recommended that, owing to the medical questions involved in the proposed act, the act be so drawn that there shall be medical representation upon the Commission.

F. J. COTTON,  
W. H. MERRILL,  
F. W. ANTHONY.

## Miscellany.

### SOCIETY NOTICES.

**THE BOSTON CITY HOSPITAL.** The Boston City Hospital Medical Meeting, to be held in the Surgical Amphitheatre, Thursday, Dec. 14, at 8.15 o'clock, p.m., will discuss "The Laboratory and Clinical Aspects of Acute and Chronic Nephritis." Pathology, Dr. F. R. Mallory; "Clinical Aspects," Dr. Henry Jackson; "Renal Efficiency," Dr. J. P. O'Hare. Physicians and medical students are invited to attend. Hospital telephone, R.R. 7100.

**THE NORFOLK DISTRICT MEDICAL SOCIETY.** A regular meeting of the Society will be held in the Surgical Amphitheatre, Boston City Hospital, Tuesday evening, Dec. 19, at 8 o'clock sharp. Telephone R.R. 7100. Business.

Communication: A Symposium on Infantile Paralysis. "Pathology," F. B. Mallory, M.D.; "Clinical Aspects," E. H. Place, M.D.; "After-treatment," J. J. Thomas, M.D. Dr. Place will give a ward visit from 4.30 to 5.30 p.m.

BRADFORD KENT, M.D., *Secretary*.

NEW ENGLAND PEDIATRIC SOCIETY.—The forty-fifth meeting of the New England Pediatric Society will be held in the Boston Medical Library, Friday, Dec. 20, at 8.15 p.m.

I. Report of Council and nomination of officers.

II. The following papers will be read:

1. Case report, Wyman Whittemore, M.D., Boston;
2. "Some Observations with Sour Milk Feeding," C. K. Johnson, M.D., Burlington, Vt.;
3. "Difficulties in the Diagnosis of Diseases of the Hip-Joint," A. T. Legg, M.D., Boston;
4. "Should All Milk be Pasteurized?" Richard S. Eustis, M.D., Boston.

III. Election of officers.

Light refreshments will be served after the meeting.

A. C. EASTMAN, M.D., *President*.

RICHARD M. SMITH, M.D., *Secretary*.

HARVEY SOCIETY.—The fourth lecture in the current series before the Harvey Society will be delivered at the New York Academy of Medicine on Saturday evening, December 16, by Prof. Henry H. Donaldson of the Wistar Institute of Anatomy and Biology, on "Growth Changes in the Mammalian Nervous System."

#### MASSACHUSETTS MEDICAL SOCIETY.

##### SPECIAL MEETING OF THE COUNCIL.

There will be a special meeting of the Council in Sprague Hall, Boston Medical Library, Wednesday, Dec. 20, 1916, at 11 o'clock, A.M., to consider the proposed legislation by the Massachusetts General Court on Industrial Health Insurance. The attention of Councilors is directed to the "Dofen Bill," the full text of which may be found in the BOSTON MEDICAL AND SURGICAL JOURNAL of Dec. 7, 1916, under "Miscellaneous." A special number of the JOURNAL, devoted to Social Insurance, will be issued on Tuesday, Dec. 19, instead of on Thursday, Dec. 21, the regular date of issue.

WALTER L. BURRAGE, M.D., *Secretary*.

Boston, Dec. 13, 1916.

#### HARVARD UNIVERSITY MEDICAL SCHOOL.

##### HARVARD MEDICAL MEETINGS.

First Meeting Friday Evening, Dec. 15, 8 p.m.  
A Amphitheatre.

A series of meetings is being arranged by the Harvard Medical School at which each department will, in turn, give an account of the departmental activities, both in research and in teaching. In this way it is hoped that members of the teaching staff, graduates and friends of the School may be kept fully informed of what is going on.

The first meeting will be held on Friday evening, Dec. 15, at 8 p.m., in the amphitheatre in Building A. The Department of Pathology will have charge of the meeting. The following addresses will be made:

Dr. Wolbach: "General Survey of the Department of Pathology and Methods of Teaching;" "Studies in Rocky Mountain Spotted Fever."

Dr. Wright: "Recent Work on Blood Forming Organs—Normal and Pathological."

Dr. Mallory: "The Value of Hospital Laboratories to Teaching and Research with Examples Illustrated by Lantern Slides."

Light refreshments will be served in the Faculty Room after the meeting.

EDWARD H. BRADFORD, M.D., *Dean*.

#### APPOINTMENTS.

UNIVERSITY OF ALABAMA.—Dr. Joseph M. Thüringer has been appointed professor of anatomy, and Dr. Claude W. Mitchell, professor of physiology and pharmacology in the University of Alabama Medical School.

UNIVERSITY OF ILLINOIS.—Dr. L. V. Heilbrum has been appointed instructor in microscopic anatomy at the University of Illinois Medical School.

#### RECENT DEATHS.

DR. GEORGE DOUGLASS RAMSAY, who died at Newport, R. I., on November 27, was born in New York City in 1869. He was a surgeon major in the United States Volunteer Army during the Spanish American War and a member of the United States Medical Reserve Corps.

DR. FRANCIS JOSEPH KEANY died at his home in Boston, November 23. The son of Matthew Keany, a prominent North End politician and property owner, he was born in Boston, March 1, 1866, was educated in the public schools and in Boston College, from which he was graduated in 1889. After graduating from the Harvard Medical School in 1892, he spent a year at the Rotunda Hospital in Dublin, and three years in Vienna, studying dermatology. He was dermatologist to the Carney Hospital and to the Boston City Hospital, and consulting dermatologist to St. Elizabeth's Hospital, and had served as a trustee of the City Hospital since 1897. He held the position of professor of dermatology to Tufts College Medical School. He held membership in the Massachusetts Medical Society, the Boston Athletic Association, and the Clover Club. His widow and three children survive him.

DR. J. PICOT, who died in France on September 26, 1916, was born in the department of Meurthe-et-Moselle in 1839. He obtained his medical degree from the University of Strassbourg and in 1872 was appointed deputy professor of medicine at Tours. In 1877 he was awarded the Montyon prize by the Institute of France for his work on clinical pathology. In 1878 he was appointed professor of pathology at the University of Bordeaux, and in 1879 professor of clinical medicine. He was elected a corresponding member of the French Institute in 1891, and in 1899 received the cross of the Legion of Honor. He was one of the founders of the Gazette Hebdomadaire des Sciences Médicales de Bordeaux.

DR. HARRY PRINGLE ROBINSON, a Fellow of the Massachusetts Medical Society, died at his home in Amesbury, Nov. 28, following an operation for appendicitis. He was a graduate of Harvard Medical School in the class of 1902, and was 40 years old. He is survived by his widow.

DR. WALTER S. SUTTON, who died in Kansas City on November 10, was professor of surgery at the University of Kansas. He was best known to biologists for his discovery of the mechanism of Mendelian inheritance in germ cells.

DR. JOHN EDWIN WALKER, who died on November 22, at Thomaston, Maine, was born in Union, Me., on Feb. 23, 1828. He received the degree of A.B. in 1881 and that of M.D. in 1884 from Bowdoin University. He had practised his profession in Thomaston since 1881, and for over twenty-five years had been physician to the Maine State Prison in that city. He was a member of the American Academy of Medicine, the American Medical Association, the Maine Medical Association, the Maine Academy of Medicine and Science, and the Knox County Medical Society.

### Address.

## THE WORKINGMEN'S COMPENSATION ACT.

By JOHN C. CROSBY, PITTSFIELD, MASS.,  
*Justice, Massachusetts Supreme Court.*

THE Workingmen's Compensation Act deals with a comparatively recent piece of legislation about which the people, independently of members of the legal profession, have a very limited knowledge. Its importance and scope is so far-reaching as to make a general knowledge of its purpose and practical operation desirable, if not necessary, to every citizen. The importance attached to legislation affecting liability, whether civil or criminal, of employers toward their workmen for injuries sustained by the latter in the course of their employment, marks an epoch in our history. Slowly, the workman, the man who earns his livelihood by his arms and his legs, on a weekly or daily wage, has forced himself to the front and demanded of the two sources of the law, the legislator and the judge, that in consideration of his employment, and the facts of the case as they press upon the owner of the arms and legs, shall have due prominence given them.

Compensation laws look at a worker as an economic machine, a mere earner of wages; they view his nerves, his eyes, his hands and feet simply as a means of producing something of value. If his occupation takes his life, the loss

of his dependents is to be measured by a part of the wages which it is assumed he would, if alive, have earned and used for their benefit. Maiming, disfigurement and loss of the enjoyments of life are not under the theory of the law elements of damage. The evidence is plenary that the old code is illogical and unjust, a breeder of wasteful litigation and pauperism; of unnecessary antagonism between employer and workmen, of low and unprofessional ideals in the legal and medical professions.

It is a matter of common knowledge that modern industrialism is characterized by a frightful destruction of life, limb and health; nobody knows how many fatal and serious accidents there are in the industries of the United States, although there is an immense statistical literature on that subject, and in the course of another decade we shall probably have something approximating accurate figures; but we do know that the fatal accidents run into the tens of thousands, and the serious accidents probably into the hundreds of thousands. The gist of the new theory is that the industries that take this toll of life and limb ought to pay to the victims and their dependents some part of the lost earning power thus destroyed; that every industry should charge that cost as a part of its expense of production. Industries must and do bear the risk of accidents and destruction as to their machinery, tools and animals; they ought to bear some part of similar economic losses now falling upon the human factors engaged in production.

Compensation acts treat the workman as a machine; the present law treats him worse than

\* Read before the Berkshire District Medical Society, Dec. 15, 1916.

machinery is treated. On both sides the idea of fault and negligence and being "to blame" is entirely eliminated, except that in our act, if the employee is injured by reason of his own serious and wilful misconduct, he gets nothing. Correlatively, the employer, guilty in a like manner, must pay into the insurance fund enough to double the compensation otherwise payable to the victim. It is a mere incident whether the claims of the victim are made directly against the employer, as under the English system, and under many of the other American acts, or whether the claim is made against the insurance association into which employers pay premiums, graded in accordance with the accident risk. In either event, the employer is dealt with simply as the medium of collecting from the consumer, and in distributing to victims some part of the loss in wages incident to the breakage of the human tools. The gist of the theory is that this special tax should be levied upon industries for the benefit of the victims of accidents in those industries.

There are those who are opposed to legislation such as is embodied in compensation acts; in the first place, upon the ground that the employer should not be obliged to contribute to employees who are injured without any fault of the employer, and because, even if constitutional and not in violation of the fourteenth amendment, in effect it involves taking the employer's property from him without due process of law. There is another class of people, who may be styled "individualists," who object to legislation of this character, in that it establishes a species of guardianship over the employee; that it limits individual freedom and responsibility, and is "contrary to the genius of American institutions."

The objection to this kind of legislation goes upon the theory of the independence of others, and of conditions created and controlled by others; that it takes away, as a practical matter, freedom of choice and self-reliance; it is said that every man should be allowed to work out his own salvation without dictation, interference or control, by the state, in matters which so nearly concern his personal welfare.

The theory of "individualism," as taught by these philosophers, is that "that government is best which governs least"; that individuals should be left to use the powers, and only the powers, which God has given them, subject only to the restraining hand of government to see that no individual encroaches upon the rights of another individual. On this theory, grants of special powers to one set of individuals are as objectionable as restraint of the natural powers of other classes; there can be no doubt that such legislation is in sharp contrast with the theory of the limitations of a government laid down by John Stuart Mill. However logical and sound this theory of "individualism" was in early times, changed conditions have made necessary

and justifiable a wide departure from old theories.

In this age of industrialism somebody must bear the burden of the industrial accidents which are found to be an inevitable incident of modern industry. Manifestly, it is just that that burden should be thrown upon the consumer in the price of the product; to put a liability upon the employer is only a means, and apparently a most direct and effective means, of making the price of the product include the cost of the waste of the human tools necessarily employed in that production. In the last analysis the Workmen's Compensation Acts are no more socialistic or destructive of individualism than many of our laws which have been in existence from the beginning. There is no justification for taxing the community to support the insane and paupers, the idle and vicious, the unfortunate of all classes, except that the general welfare of society demands it.

It seems to me that the law is upon a proper and logical industrial basis; it deals with the problem as an insurance problem and not as a fault problem; it recognizes that accidents, whether due to the employers' fault, employees' fault, the risks of the business, or a combination of causes known and unknown, are certain to happen, and that their happening is an event of social importance, not a mere individual misfortune; it deals with these risks of life just as the Germans and ourselves have dealt with education as a great social need.

The State recognizes that insurance is as much a necessity for social welfare as education is a necessity. The theory of individualism is that each person should take care of himself, and that society will profit out of his so caring for himself. This theory fails when applied to industrial accidents under modern conditions. The sound theory of individualism or collectivism, or whatever one chooses to call it, is that within certain proper limits the mass of the people should be compelled to take care of themselves, but where they are unable to do so under special conditions, and loss of human life, and maimed and crippled men, women and children result, I believe it to be the duty of the State in the interest of the welfare of its people to remedy, so far as possible, such conditions by appropriate legislation.

The great wave of industrialism which has spread over Europe and this country, demands today a solution of problems between man and man which require broader views and ideas than have heretofore prevailed among legislators and judges. The enormous use of machinery, more or less dangerous, has contributed largely to the changed conditions; it has produced, and is annually producing, a vast army who have been maimed by its use; it presents a woeful sight, and is a melancholy commentary on our methods of production. At the outset it is important briefly to consider the remedies which exist,

independently of compensation acts, under which workmen are entitled to recover for personal injuries. At common law, the master is liable in damages for personal injuries suffered by his servant, received in the course of his employment, caused by the negligence of the employer, the servant himself being in the exercise of due care. The basis of such liability is negligence in the breach of duty: it is the legal duty I owe my neighbor not to hurt him. The common law of England, which, generally speaking, is the common law of this country, as well as that of the various states of the Union, recognizes the liability of the master for injury to the servant caused by the negligence of the former, but this rule is hedged about with certain important exceptions; first, the servant is precluded from recovery if his negligence, however slight, contributed to his injury; second, a man assumes the known risks of his employment; and third, the master is not liable for an injury received by a workman which is occasioned by the negligence of a fellow servant.

The injustice which often arose from the application of these rules of the common law in actions brought thereunder has resulted in the last few years in legislation the effect of which has been to modify the harsh and rigorous rules of the common law; these modifications are contained in enactments known as employers' liability acts.

In England an act of this kind was passed in 1880, and was intended to remedy the injustice of which the working population had long complained. In Massachusetts a similar act, patterned after the English act, was enacted by the Legislature in 1887. The writer happened to be a member of the House of Representatives during that year. Nearly all the states of the Union have enacted similar legislation.

Without undertaking to point out in detail the provisions of our Employers' Liability Act it is sufficient to say that it modified the common law, and permitted the recovery of damages by a workman for personal injuries, in many instances where no remedy previously had existed. These rules of law were established many years ago and were in force before the days of rapidly-moving machinery, and before the advent of electricity and the locomotive, and the result was that great injustice was done to many injured workmen under modern conditions by reason of the fact that these rules of law were not applicable to the existing situation, the loss to the injured employee being, in a great majority of cases, just as serious and as great whether he was injured under circumstances that permitted of recovery or not; and it so happened that a large percentage of people killed and injured were without any remedy because of the fact of the intervening negligence of a fellow servant, the assumption of the risk, or contributory negligence on the part of the injured employee; besides, where the injured

employee sought a remedy in court, it was attended with long delay and expense, the outcome was doubtful and conjectural, and the employer was always exposed to the hazard of a tremendous verdict, which to him might mean bankruptcy. In case of trial it meant a disarrangement of the factory while the men were attending court, a long period of waiting, with no compensation; and in many cases practical experience has shown that men injured under circumstances almost similar received compensation in some cases and in others received nothing, so that the law was distrusted and at times subject to contempt and ridicule.

It followed, that under the common law and the Employers' Liability Act many injured people were without remedy; it also resulted in great inequality by which sometimes a man was entitled to recover, when another, equally seriously injured, under circumstances which to the lay mind would seem to be practically the same, was held to be without remedy. I have in mind an instance which happened not many years ago where three trainmen were injured, each suffering the loss of an arm. While the injury in each instance was the same, one of the three was given a verdict of \$5,000 by a jury, the second was awarded \$2000, and the third received nothing.

A knowledge of these cases by the public, and especially by the men themselves, could not have engendered as much respect for the justice and equality of the law, as might be the case under other circumstances. Notwithstanding the additional remedies provided under the Employers' Liability Acts, the general opinion long has been prevalent both in this country and Europe that the law in force in industrial employment was fundamentally wrong and unwise and in need of radical change. The workman injured in his employment must of necessity bear the burden of his injury; the pain and suffering are his, and no system of law can change or shift that burden. Still, if his injury be not one which he has wilfully brought upon himself, but which has arisen from the hazard of his work, it was felt that the workman should be so placed by the law that he should have the right to call for and receive such prompt and certain compensation as would keep him and those dependent upon him from destitution.

On the continent of Europe, the law as to employers' liability, as distinguished from any scheme for compulsory insurance of workmen against accident, is substantially the same as our own common law, that is to say, it is a branch of the law of negligence. In regard to some special trades and occupations, there has been in many countries of Europe special legislation affecting employers' responsibilities, but apart from these enactments, the law of Europe is, for the most part, in accordance with the principles of the French Civil Code, which for more than a hundred years still remains the law of France.

The first workmen's compensation act to be enacted was by the Imperial Parliament in Germany in 1885. This law is based upon the insurance plan; it is compulsory, and commonly called the German system of insurance against accidents. It consists of two sister measures,—the sickness insurance act and the accident insurance act. These two acts are now in force, and together form the German scheme of which so much has been said and written. Under the Sickness Insurance Act the employer is bound to insure his workmen and pay the whole of the premiums in the first instance, but he is permitted to deduct from the wages of his workmen two-thirds of the cost, the remaining one-third being borne by the employer himself. A great majority of the accidents which occur there are dealt with under this act. The Accident Insurance Act includes cases where there is not a recovery within a period of thirteen weeks, and imposes upon the employer the obligation of providing the whole of the funds necessary to take care of those cases. It is seen, therefore, that for the first thirteen weeks of an accident, the workman pays two-thirds and the employer one-third, and in cases requiring further assistance the employer pays all.

The chief characteristics of the German system are that it is compulsory, mutual insurance, and that compensation is provided in every case except where the injury is intentionally self-inflicted. There was a great deal of opposition to this act in Germany when it was first proposed; it was claimed to be unfair to workers and it was said it would put such tax on industry that if the act became a law, Germany would lose its industrial supremacy. The act has been in operation in Germany for thirty years, and has met with the approval of every sincere friend of the German empire; Germany has not lost its industrial supremacy, and the act is regarded there as a most beneficial piece of legislation in behalf of the great mass of the people, protecting them in one of the most important exigencies of life; besides it has proved to be a bond of harmony between labor and capital, and employer and employee.

The first workmen's compensation act in England was passed in 1897, and in 1906 the original act was repealed and a new act was enacted by Parliament broader in principle and more extensive in its scope.

This subject, several years ago, received the earnest attention of our federal government, and in 1908 President Roosevelt, in a well-known message declared it to be a national duty to pass laws which would bring relief to injured workmen, and indicated at the same time the duty of the legislatures of the several states. He said: "I also very urgently advise that a comprehensive act should be passed providing for compensation by the government to all employees injured in government service. Under present conditions an injured workman in the

employ of the government has no remedy, and the entire burden of the accident falls on the helpless man, his wife and his young children. This is an outrage. It is a matter of humiliation to the nation that there should not be on our statute books provision to meet and partly to atone for cruel misfortune when it comes to a man through no fault of his own when faithfully serving the public. In no other prominent industrial country in the world could such gross injustice occur, for almost all the civilized nations have enacted legislation embodying the complete recognition of the principle which places the entire trade risk for industrial accidents (excluding, of course, accidents due to wilful misconduct by the employee) on the industry as represented by the employer, which in this case is the government. In all these countries the principle applies to the government just as much as to the private employer. Under no circumstances should the injured employee or his surviving dependents be required to bring suit against the government, nor should there be the requirement, in order to insure recovery, that negligence in some form on the part of the government should be shown. Our proposition is not to confer the right of action upon the government's employee, but to secure him a suitable provision against injuries received in the course of his employment. The burden of the trade risk should be placed upon the government. Exactly as the workman is entitled to his wages, so he should be entitled to indemnity for injuries sustained in the natural course of his labor. . . . The same broad principle which should apply to the government should ultimately be made applicable to all private employers. Where the nation has the power it should enact laws to this effect. Where the states alone have the power, they should enact the laws."

In his annual message to the legislature of the state of New York on January 1, 1909, Governor Hughes said: "I believe that it would be salutary to go further in accordance with the principles which have been announced in some of the jurisdictions, and in the case of injuries sustained by adults by reason of conditions created or permitted in violation of the labor law, to preclude a defense upon the ground of the assumption of risk by the employee. . . . I also recommend that provision be made for special and extra inquiry into the questions relating to employers' liability and compensation for workmen's injuries; our present methods are wasteful and result in injustice. Numbers of negligence cases are prosecuted upon a basis which gives the attorneys a high percentage of recoveries; only a small percentage of the premiums paid for insurance against liability is devoted to the payment of losses; as a result the workmen do not receive proper compensation, and the employers pay large amounts that do not reach them."

Soon after the President's message, above referred to, was delivered, and on May 30, 1908, in a modified form, a workmen's compensation act was enacted by Congress. This act guaranteed to employees of the United States the right to receive from it compensation for injuries sustained in the course of their employment. Although this act is of limited application, and provides but a limited measure of relief, its benefits have been many and real; it applies only to injuries received by artisans and laborers employed in manufacturing establishments, arsenals or navy yards of the United States, or in river and harbor or fortification work, or in hazardous employment in the reclamation service and under the Isthmian Canal Commission, under the Bureau of Mines, and in the Forestry and Lighthouse Service.

While figures showing the results of this act from the time of its enactment to date are not available to the writer, still an examination of the results obtained during the first three years after its enactment will give some idea of the benefits derived under the compensation act. During the first three years it was in force, compensation was paid in 5564 cases of injury, in 165 of which the injury resulted in death, and on account of these fatal injuries \$113,000 was paid to surviving dependents; on account of non-fatal injuries \$800,000 was paid to the injured persons themselves, but these figures do not include claims arising from workmen employed on the Panama Canal.\*

The people of the Commonwealth of Massachusetts, recognizing the long-continued and increasing demand for the modification or abandonment of the common-law remedies as applicable to the relationship of employer and injured employees, and, as ever, keenly alive to all progressive and humanitarian legislation, as early as 1887 took the first step toward a better system of dealing with industrial accidents, when in that year the Massachusetts Employers' Liability Act, above referred to, was enacted. This, by the way, was the first law of its kind to be passed in the United States. The subject of still further and more advanced legislation had been under consideration by the General Court from year to year since 1887, and culminated in the appointment of a special commission of five members under a resolve enacted in 1910. This commission, composed of intelligent and able men, well qualified for the work, after long study and careful investigation, reported a draft of a bill which was in substance adopted by the Legislature in 1911, and is contained in Chapter 751 of the Acts of that year; it is the present Workmen's Compensation Act of Massachusetts, except so far as it has been perfected by subsequent amendments.

The act is a well-drawn piece of legislation, and reflects great credit on the men who framed

it. Still, difficulties have arisen in its interpretation which could not have been anticipated in advance, or, if anticipated, could not have been fully guarded against until the act was put in practical operation.

The passage of this act is a sincere attempt to remedy existing conditions, and to place personal injury cases growing out of the relation of employer and employee, upon something like a humane and scientific basis of settlement, the fundamental consideration being that, just as a machine breaks down, or a manufacturing plant goes to pieces, and the loss falls upon the industry and enters into the cost of production, so, when an employee is killed or injured, the loss should fall upon the industry and become a part of the cost of production. This is the theory upon which this and similar legislation is based. Conditions are such that the employer can always protect himself against losses of this nature by insuring his employees, while conditions are such that a great majority of the employees either cannot or will not protect themselves against such losses.

Injuries to workmen in the course of their employment may be due to negligence or to accident; where negligence is the cause, the fault may be that of the workman or of his employer, or of a fellow workman, or even of a stranger; where pure accident is the cause no one is at fault. In all cases, the suffering and the loss fall on the injured person and his dependents, except so far as the law permits the loss to be compensated. The old law, formulated at a time when industrial operations were limited and simple, and conducted in small establishments, where responsibility could easily be fixed, is wholly inapplicable to modern conditions; the altered situation growing out of the immense changes made in industrial conditions has brought a realization of the great injustice worked by the old rules of law. Irrespective of the question of negligence, whether it was that of the employee, the employer, the fellow servant or the stranger, and irrespective of the risks incident to the dangerous nature of the occupation, it was recognized as grossly unjust that the sufferer alone should be allowed to bear the entire consequences, and all the burdens, of an industrial accident or injury; it was seen that the employment itself, if not the cause of the injury, furnished at least the occasion or the condition without which it could not have occurred, and so it has in recent years become the settled conviction of thinking people that the financial loss occasioned by an injury received in the course of employment is a proper charge against the industry itself, and that where such injury is not plainly due to the fault or misconduct of the injured person, the employer or that means is provided whereby the burden in such cases is shifted to a certain extent from a single person and distributed among many persons.

The Workmen's Compensation Act in

\* At the last session of Congress the act was amended so that it should apply to the act were enacted.

Massachusetts went into effect on July 1, 1912, and has been in practical operation ever since that time. It is to be remembered that if a person is killed or injured by reason of an accident which arose out of, or in the course of, employment, that he or (in case of his death) those dependent upon him for support, are entitled to compensation without reference to the questions whether his own carelessness contributed to the injury, or whether he assumed the risk, or whether the injury was due to the negligence of a fellow servant. Under the act all these questions are swept away. While it would be impossible to discuss in detail all the provisions of the act, or the many difficult and interesting questions which have arisen under it, a brief outline of its provisions may be given.

The Massachusetts act is modelled in part on the German and in part on the English systems. It is more like the German plan, but it is unlike both in that, in form at least, it is elective and not compulsory. Our act, while it applies generally to farm laborers and domestic servants, still as to these two classes it leaves to the employer the old defenses of contributory negligence, assumption of risk and negligence of the fellow servant. It is also to be observed that the act does not apply to those occupying positions in the public service; accordingly, school teachers, policemen and firemen are not entitled to compensation for injuries thereunder, although employees of a municipality engaged in a gainful pursuit, like the development and sale of electricity or water for profit, are covered by the law.

It provides as follows: First, from the standpoint of the employer. The employer, in the first instance, has the right to decide whether he will or will not give his employees the benefit of the act. He can do nothing; that is to say, in the event he decides not to give his workers the benefit of the act, and a man in his employment is injured, the employee is no longer obliged to prove his own care; so, too, questions as to the negligence of a fellow servant, or the assumption of the risk, are both immaterial. The employee has only one thing to prove in order to be entitled to compensation, and that one thing is the negligence of the defendant, which may be direct or indirect, his own personal negligence or the negligence of his servant. In other words, if an employer does not insure his help, the employee injured in his employ can recover if he can establish, to the satisfaction of the court, that the employer was in any way guilty of negligence. The employer, on the other hand, if he desires to give his men the benefit of the act does so by taking out a policy of insurance in one of the various insurance companies authorized to do business in the State; the employer pays his premium, and he is relieved from all responsibility to respond in damages if a person in his employ is injured, the insurance company being substituted for the

employer and assuming all liability. There is no exception to this, and that is that where the employer insures his men, and is himself guilty of serious and wilful misconduct; if that be proved he must pay to the injured employee double compensation, one-half of which is paid by the insurance company and the other half by the employer. This, however, is only in a case where there is serious and wilful misconduct on his part or on the part of his superintendent.

Second, from the standpoint of the employee: As has already been stated, if the employer does not insure the employee, the employee can in this case recover damages in the courts by proof of negligence, and merely upon proof of negligence of the employer. If, however, the employer insures his employees, the employee has the right to reject the compensation given under the act, and then has all the rights which he had prior to the first day of July, 1912, under the common law as distinguished from the statutes of the Commonwealth. In other words, in the case of the employer insuring his employees, and the employees rejecting the benefits of the Workingmen's Compensation Act, an injured employee can recover compensation if he can establish his own care, and the negligence of the employer, and that there is no assumption of risk and no negligence of a fellow servant; under such circumstances he is entitled to recover such compensation as a jury may award him. But it is to be noticed that in this case such employees are exclusively under the common law, as distinguished from the statutes of the Commonwealth; they have all their common-law rights but no statutory rights, and compensation for death being a statutory right, and not a common-law right, if an employee has rejected the provisions of the Workingmen's Compensation Act, no recovery can be had by his dependents in case of his death. If, on the other hand, the employee is injured under the act, and accepts the provisions, he thereby, in case of injury, recovers practically two-thirds of his wages during disability; and if he loses a leg or an arm, an additional one-half of his wages for a period of a hundred weeks down to twelve weeks, according to the extent of the injury; but in all cases he recovers two-thirds of his wages during disability, not to exceed, however, \$4000, or covering a period exceeding five hundred weeks, the maximum weekly compensation being \$10 per week, and the minimum compensation being \$4 per week. The injured workman is also entitled during the first two weeks after his injury to hospital and medical services free of charge.

It is to be noted, however, that, aside from furnishing to the injured workmen medical and hospital services free of charge, the act allows nothing for the first two weeks after the injury. This period is sometimes called the "waiting period." By an amendment passed

by the last legislature, which takes effect January 1, 1917, this period is limited to ten days. The English act allows nothing for the first week, unless the injury lasts two weeks, which results in many injuries lasting two weeks, and in a good deal of petty malingering and unnecessary expense in investigating trifling injuries. These petty injuries in the aggregate are said to cost English industries a large sum.

Another feature of our act which should be referred to is that, although as a rule, the compensation awarded is given to the injured workman, or, in case of his death, to his dependents, in weekly payments, it is provided, "in unusual cases" a lump sum may be paid if agreed to by all parties in interest and approved by the Industrial Accident Board.

The result of the act has been practically to eliminate the bringing of actions, either at common law or under the Employers' Liability Act, for personal injuries by workmen against their employers. This has resulted in relieving the courts of a very large number of cases which heretofore have occupied their attention. At the same time it is doubtful if there has been any decrease in litigation, because of the fact that a large number of cases have arisen growing out of the Workmen's Compensation Act, and which involve the construction and interpretation of its provisions, the law being of so recent enactment that questions are constantly arising as to its meaning, and as to whether many cases which have arisen do or do not come within its provisions. Where the injury results in death, and compensation is awarded to those who were dependent upon the deceased workman, a trust fund is created, which is secure from unfortunate investments, and debts, and is unassignable, the beneficiary is entitled to weekly payments for a period not exceeding five hundred weeks. The benefits arising by means of this method of compensation are manifest. The act has eliminated all speculation which had previously existed in personal injury cases on the part of anybody; the compensation comes from the employer direct to the pockets and homes of the injured employees, without any diminution, or expense or delay, and every injured employee of the same earning capacity, and receiving the same amount of wages throughout the Commonwealth, suffering from the same disability, is entitled to exactly the same compensation.

In its practical workings the act has taken away much of the bitterness between labor and capital occasioned by personal injury cases in the courts, and has brought about harmony between the injured employee and his employer. The act provides in practical effect for industrial insurance paid for by the employer exclusively for the benefit of employees. Aside from the pecuniary relief which is afforded to the injured workman, one of the great benefits which have come from this legislation, is the improve-

ment which has been made in the adoption of safety devices and appliances in factories and other places where labor is employed; great improvements have been made in this direction, with the result that the number of accidents in industrial occupations is constantly decreasing. To my mind this is of as great, if not greater, importance than the mere payment of compensation for injuries, because the great object to be accomplished by the act is, not compensation, but prevention; and while it is well to compensate a man if he becomes seriously injured, it is infinitely better so to guard the machinery upon which he is employed, and the place where he is put to work, that he may go through life unharmed.

The act also provides for the establishment of an insurance company, known as the Massachusetts Employers' Insurance Association, in which employers of labor are entitled to take out insurance in conformity with the provisions of the act. Employers are not limited to this state insurance association for the procurement of policies, but under the act are authorized to take out insurance in any liability insurance company authorized to do business within this Commonwealth.

In 1909, before the act took effect, practically only 36% of the money paid by employers or Massachusetts to settle all claims for injuries was paid to the injured public and to injured employees; in other words, 64% was kept by the insurance companies for the payment of expenses, premiums, and for profit.

The act provides for the establishment of an Industrial Accident Board, consisting of five members. This board administers the law without the necessity of the intervention of anybody to represent parties who come before it; the proceedings are informal, without technical pleadings or rules of practice, and the law is administered in a plain, simple, matter-of-fact way, in order that justice may be done. Before the compensation act was adopted, it met with the opposition of many employers of labor, who opposed it upon the ground that it would result in an undue and excessive burden upon them, because of the large premiums which they would be required to pay for insurance. The act has been in force for three years and a half, and in practice it has been shown that the expense for premiums has not been greatly in excess of the cost before the act took effect, and in some cases the amounts so paid have been less under the act than before its adoption.

During the year before the Workmen's Compensation Act became effective there was paid in premiums on liability insurance \$2,779,100. During the year ending June 30, 1911, the payrolls, which represent the earnings of injured employees, amounted to \$150,000,000, and the premium cost, based upon the payroll of about 1%, amounted to \$1,500,000. The cost is intended to be shifted to the consumer. Such

cost of insurance if placed upon the consumer, according to the returns for the year 1913, would amount to 18 cents upon a hundred-dollar purchase. This includes both the cost of losses and the cost of insurance administration.

It is doubtless true that in rare instances compensation is granted to unworthy persons. A case is given under the German act of a man who hoodwinked the insurance authorities in Berlin for the payment of 50% of his average weekly wages for a disability arising out of industry, and who was accidentally discovered to be following the occupation of an acrobat in Alsace. Another case is quoted where a man drawing a disability payment for an injured elbow was at the same time, under another name, earning a living as a pugilist.

The purpose of our act and its practical operation is well stated in Gould's case, reported in 215 Mass. 480, which is one of the first cases to be considered on appeal to our Supreme Judicial Court. It was said at page 482: "One main purpose of the act is to establish between employer and employee, in place of the common-law or statutory remedy for personal injury, which is based upon tort, a system whereby compensation for all personal injuries or death of the employee received in the course of and arising out of his employment, whether through unavoidable accident, negligence or otherwise (except through his serious and wilful misconduct), shall be determined forthwith by a public board and paid by the insurer. For the accomplishment of these ends, a simple method is furnished, operating without delay or unnecessary formality. . . the compensation is to be paid, not directly by the employer, but by the insurer, who is either the 'Massachusetts Employees' Insurance Association,' created by part 4 of the act, or any liability insurance company authorized to do business within the Commonwealth. The employee has no immediate relation with the insurer; he is the beneficiary under a contract between the employer and the insurer."

The Commonwealth was fortunate in the selection, as the first chairman of the Industrial Accident Board, of Hon. James B. Carroll of Springfield, now a justice of the Supreme Judicial Court. Judge Carroll brought to the Board a wide knowledge of the relations which exist between employer and workmen; he formulated the practice of the Board, and was largely instrumental in placing a humane and just interpretation upon the provisions of the act; his decisions under it have been very generally sustained by our highest court, when appeals thereto have been taken. His painstaking and intelligent work as the chairman of the Board has largely contributed to the success which has been attained in its practical operation.

This Board administers the law which affects the rights of about 900,000 workmen and

women, 27,000 employers of labor, and 27 large insurance corporations; also capital amounting to billions of dollars, products valued at billions more, wages above the one-half billion mark; and the rights of nearly all the working people of our Commonwealth and their families are involved in the administration of the Workingmen's Compensation Act, which I believe to be one of the most beneficent pieces of social welfare legislation heretofore enacted.

It is estimated by the Board that less than 150,000 employees are not protected by the act, but may bring action under the general law, with the three defenses of contributory negligence, negligence of a fellow servant, and assumption of the risk eliminated.

The payments under the act during the last full year that the act has been in force are as follows:

To employees receiving non-fatal injuries	\$1,502,185.43
To fatally injured employees and dependents	748,493.57
To physicians and surgeons for services	587,769.99
Total	\$2,838,448.99

When we realize that industry in Massachusetts takes a toll of the lives of five hundred employees during the course of each year, and leaves behind two thousand widows, orphans, fathers, mothers, sisters, brothers and other dependents; that during every minute of the entire year a small army of at least four thousand working people are idle as the result of industrial injuries, and that approximately 100,000 people receive personal injuries annually,—ranging from serious to severe and fatal,—we may get some idea of the importance of the work devolving upon the Industrial Accident Board. The wage loss per day in this Commonwealth from personal injuries is conservatively estimated at \$10,000; the economic loss per day at more than three times that figure, and the loss of future earning power, of opportunity to live out the full period of life, and to enjoy the society of family and fellow men, is incalculable.

While this legislation is of recent enactment, I believe that it has come to stay. Thirty-one states and two territories in the Union have adopted laws which provide for the payment of compensation to injured workmen and their families when the risks of employment cause personal injuries which deprive them temporarily or permanently of their ability to earn a living, and it is a source of pride and satisfaction to know that many of our sister states have used the Massachusetts law as a model and the basis of their own; many commissions entrusted with the investigation of this subject, and the carrying out of the law in states where it has been enacted, are constantly visiting this Commonwealth to obtain advanced ideas as how best to deal with their own acts, and to study the practical and successful manner in which the law in Massachusetts has been administered.

Perhaps in no other state has an elective act been so generally accepted by employers and employees alike as in Massachusetts; about 80% of the working people of this Commonwealth are covered by insurance under the statute, and the balance of these workers are favorably affected by the law, since the non-insuring employer is answerable for personal injuries caused to his employees, and stripped of the common-law defenses which have been heretofore referred to; because these defenses are no longer available, and the employer who is sued for personal injuries has no ground of defense if it can be shown that the injury was due to his negligence. Undoubtedly the comparatively small number of employers who have heretofore failed to become subscribers under the act will sooner or later practically all come within its provisions, thereby escaping the disadvantages under which they labor when sued at common law by an injured employee. The working people of Massachusetts have come to look upon the operations of the Industrial Accident Board as an industrial court, to which they may turn with confidence in the belief that their rights, and the rights of their families, will be safeguarded; they have shown a desire to see this important commission protected from all improper influences, and desire to have it kept out of the domain of partisan politics. This desire on their part is laudable when it is considered that the Board has almost an exclusive right to adjudicate the claims which arise out of injuries to the immense number of working people protected by the provisions of the law. Its decisions are not subject to review, except by the Supreme Judicial Court, they are final as to findings of fact; still if there is no evidence upon which such findings may rest, their decisions are subject to reversal by the Supreme Judicial Court on questions of law. The amount of work which is cast upon this Board is very large, necessitating frequent evening sessions in order that the urgent claims of injured workmen may be speedily adjudicated, that they may have the compensation which they may be entitled to receive.

The number of reported injuries has grown from 89,000 during the first year to more than 100,000 in the third year of the act, and even the latter high figure is certain to be increased because of the continued increase in the number of employers accepting insurance and reporting injuries to their employees. The number of employers who became insured has increased from 10,000 during the first year to 27,000 in the third year of the act. The number of employees who are covered by insurance has grown from 600,000 to 900,000. The number of arbitration hearings has increased from 400 to 1200. The number of conferences on disputed cases presided over by the members of the Board has grown, from an insignificant number during the first year, to 3000 in the present year. The

number of disputed doctors' bills has increased from less than a hundred during the first year to more than one thousand in the third year. The number of full Board cases has increased from 120 in the first year to 600 during the present year. The number of matters considered at each full Board meeting has increased from less than a dozen to forty. The number of agreements providing for the payment of compensation coming before the Board for approval has increased from 8000 during the first year to 25,000 during the present year. New problems constantly are arising regarding fees of physicians, charges of hospitals, rights of employees, rights of insurance, rights of employers,—all of which affect the general right of the public and the welfare of the Commonwealth, and have a material bearing upon the cost of insurance under those benefits which widows, orphans, parents and other dependents of employees, and the latter, themselves, may receive.

In the performance of these many duties, the Board is required to protect both the employer and the employee from any infringement upon the rights to which each is entitled under the act, and the fact that the Board has been able to administer the law fairly, despite the many problems arising because of its novel and complex provisions, speaks well for the integrity and efficiency of its organization and personnel. The Industrial Accident Board should not be hampered by changes due to political expediency, but should be encouraged to work out constructively the many problems which constantly confront it.

While this paper is already unconscionably lengthy, dreary and uninteresting, I feel as if I ought, before closing, briefly to refer to a few cases which have arisen in the English courts, as well as in our own, involving the construction of the act.

It is to be borne in mind that to bring a claim for compensation within the act it must appear that the employee received a personal injury, and that such injury arose out of and in the course of, his (the employee's) employment, and that the condition of the employee is due to the injury as a proximate cause.

The English act provides that the personal injury received shall be "by accident." These words "by accident" are not found in the Massachusetts statute. Take a few illustrations from the English courts: It has been held by them that nervous shock caused by accident was within the act, and that a collier who was overcome by the sight of injuries sustained by a fellow workman could recover upon the ground that mental, nervous or hysterical effects of an accident are just as much included as physical results.

It has been held that a man who was murdered was killed by "accident" within the meaning of the act. This decision was made by the House of Lords affirming the Irish Court of

Appeals. A collier working in a narrow seam which involved constant kneeling, a small piece of coal found its way up his trousers and worked into his knee, causing blood poisoning. Held to be within the act. A workman shifting lumber,—during the night planks froze together, and not realizing the fact, he ruptured himself in trying to lift a plank. Held the case was within the act. Death by lightning was held to be an accident; it was held by the House of Lords that heat stroke caused by the rays of heat from the boiler of a steamship, and which rendered a stoker in an enfeebled state more liable to attack, was an accident, and entitled the workman to compensation. A collier died from pneumonia following a chill brought on by having to wait for a considerable period, when overheated, near to a ventilator shaft before he could be brought to the surface. Held to be within the act. (5 B. W. C. L., 177, H. of L.)

It also has been held in England that injury caused by frost-bite is not within the meaning of the act. A contrary decision was recently handed down by our Supreme Judicial Court. A wool sorter contracted the disease of anthrax, a form of blood poisoning arising from a germ found upon certain animals. Held he was within the act.

The Supreme Judicial Court of Massachusetts is constantly reviewing cases under our act upon appeal. An employee was assaulted by a fellow workman, the latter at the time being intoxicated; the employee died as the result of the assault. Held that the injuries arose out of and in the course of his employment. An employee of a citizen, a resident of Massachusetts, was injured while out of this State. Held that the act had no extra-territorial effect, and that no compensation could be paid. An employee, the driver of a delivery wagon, after his day's work was over, was directed to drive his team to the stable. The following morning he was found some distance away in a swamp; he was unconscious, and died while in that condition. Held that his injury did not arise out of his employment. An employee at a gas plant became blind, caused by poisonous gases. Held to be within the act. An employee, a paint grinder, contracted lead poisoning. Held it was a personal injury and that he was entitled to compensation. An employee tripped while getting off an elevator and was thrown against the opposite wall of the hallway; later strangulated hernia developed and death followed. Held that the injury which caused the death arose out of and in the course of the employment. A workman, after his work for the day was ended, was offered a ride home in his employer's wagon, in accordance with a custom, and on the way he was hurt. Held that the ride was incidental to his employment and that the injury arose out of and in the course of the same. An employee, who worked nights on the seventh floor

of a building as a compositor in a printing office, where the men who worked with him were in the habit of going out upon the roof of an adjoining building owned by the employer, to cool off on hot nights; the employee was last seen alive about eleven o'clock p.m., and his body was found about four hours later on the ground six stories from the roof. It was held by the Supreme Judicial Court that his injury and subsequent death could be found to have arisen out of and in the course of his employment.

The constitutionality of acts passed for workmen's compensation has been passed upon by the highest court in many of the states of the Union, and has been uniformly sustained with one exception. The Court of Appeals of the State of New York declared the act passed by its legislature unconstitutional, on the ground that, being compulsory, it authorized a taking of property without due process of law, and was, therefore, within the constitutional inhibition. *Ives vs. South Buffalo Railroad*, 201 N. Y. 271.

An opinion was given to the Massachusetts Senate by the justices of the Supreme Judicial Court, upholding the constitutionality of our present act. In the course of this opinion it is said "There is nothing in the act which compels an employer to become a subscriber to the Association or which compels an employee to waive his right of action at common law and accept the compensation provided for in the act. In this respect, the act differs wholly, so far as the employer is concerned, from the New York statute above referred to. . . . Taking into account the non-compulsory character of the proposed act, we see nothing in any of these provisions which is not in conformity with the 14th amendment of the Federal Constitution or which infringes upon our constitution in regard to the 'taking of property without due process of law.'"

The law allowing compensation to workmen for injuries sustained in the course of their employment being of recent growth and development will undoubtedly require, from time to time, perfecting amendments. I believe it is a long step toward the betterment of social and economic conditions, and will not only result in the relief from destitution of thousands of injured workmen and their dependents, but will also be the means of the adoption of measures which will materially diminish the number of industrial accidents in Massachusetts.

### A CONSIDERATION OF WORKINGMEN'S ACCIDENT AND SICKNESS INSURANCE IN THEIR RELATION TO THE MEDICAL PROFESSION.\*

By F. J. COTTON, M.D., F.A.C.S., BOSTON.

I HAVE been asked to say something about the general problem of insurance, both as to health and accident, but realize that I am here principally because of my connection with the committee entrusted by the Council of the Massachusetts Medical Society with the task of looking out for medical interests involved in the impending legislation for compulsory sickness insurance of workmen.

I believe this form of insurance is coming, whether we like it or not, and that its coming bids fair to revolutionize medical practice in this State; probably not to the benefit of its practitioner.

It is time for us to wake up to this very grave problem; a time to do more than to vote for a motion that the chairman appoint a committee. Each of you must become a committee of one; you must inform yourselves as to what threatens and as to what *you* can do in this matter.

Now we have no experience with sickness insurance of this type in this Commonwealth or in this country, but we have had accident insurance, and should have learned something in the four years this law has been operative; for many of the problems of the two sorts of insurance are similar.

First, the law on accident insurance was passed while the profession was asleep; we were not invited and we did not rouse up and go to the party. Not only were our rights in the matter not safeguarded; they were not even mentioned; not even thought of.

Obviously this situation, as it affected the original bill, was not bettered by the changes which opened up its workings to certain interests that have never been noted for consideration of or respect for our profession or for its work.

When the bill became a law, we found ourselves in a very unfortunate predicament with no privilege safeguarded us under the law save the privilege of practising for nothing. Fortunately, the Industrial Board has been very fair-minded, has sought good medical advice and taken it, so far as was possible under the law, in regard to medical problems.

The efforts of the Board and of their medical advisory committee brought about a compromise, unsatisfactory to everyone, of course, but far better than the original situation; a compromise possible only because most of the insur-

ance companies were disposed to be very decent about it, and to forego their exact rights under the law.

Under this compromise, we have been living in reasonable peace until last spring, and might be going ahead not too unhappily were it not that one or two companies have refused to continue to waive any of their legal rights. This makes it hard for the other companies who still want to be decent, as it gives an unequal advantage in rate-making, and it has made the medical situation almost intolerable in many communities.

Just what this situation is you will hear from other speakers, who will outline their plans for betterment of the conditions, so I need not go into this further. The moral, however, is obvious!

Once we were caught napping; this must not occur again. We must see to it that we are considered and that our advice is heeded and our rights safeguarded in the adjustment of medical problems involved in impending legislation, and safeguarded in the bill to be passed; not petitioned for afterward. Lay control of medical work is not only unfair, but is stupid as well, and very apt to defeat its own ends.

Another point we have learned is that professional service is not all of it satisfactory; that some few practitioners fail in professional competency; others fail in that sense of co-operation in public service in which our profession, in its mass, has always been conspicuous. The failings of the medical profession in this matter have been overestimated, but experience of the last four years does indicate the desirability of medical supervision of work done under a general insurance scheme; mark you, I say, not lay supervision, but competent, disinterested medical supervision.

Another problem that has loomed large is the relation of hospitals to care furnished under any compensation law. In this State, some hospitals are on a private basis; some private with provision for charity patients also. In some of these the doctor is paid in full; in some he is paid on private cases, not on ward cases. But a large share of our hospitals were conceived as charities; are supported by benevolence; expect to run behind yearly, because they are dedicated to service. Such hospitals ask the doctor (and quite properly ask him) to give his services to charity patients, and in some instances, in the older charity hospitals, the staff are not paid for any of their work at all.

This variation in conditions has led to endless squabbles, and the answer is not in sight.

Trustees of charities and members of the professional staff of such charities have been unable to see why arrangements conceived for the relief of the unfortunate should be used to reduce expense accounts of commercial corporations.

No adjustment is in sight as yet, and this hos-

\* Read at a meeting of the Suffolk District Medical Society, October 25, 1916.

pital problem is one of the most difficult to adjust under any compensation scheme, whether it deal with accident or sickness compensation.

The suggestion has been made that hospitals establish industrial clinics on a pay basis; the work to be paid for by the insurer—doctors' payments included. This is feasible, and the only way apparent in which the big clinics, and many, at least, of the small ones, can be utilized without injustice. There are objections to it, but it is feasible. The present condition is likely to lead, particularly in out-patient clinics, to the swamping of facilities intended only for the hospital's usual clientele. Hospitals are usually undermanned, under-financed, and this situation is bad and must, if it get much worse, lead to poor work.

Another point is that we cannot rely on a *priori* judgment as to what the other fellow would do. *A priori* it seems obvious that the insurer would realize the purely commercial benefit in the long run of keeping up a high standard of surgical care. Some of the insurance companies have done so, and their care of their dependent injured has been intelligent and excellent.

In other instances, companies representing a considerable percentage of the risks written have shown no interest in the medical side, no interest in getting the injured man back to competency, and have seemingly regarded nothing save the keeping down of the expense account by any available method. So far has this gone that it was needful to pass an amendment providing that compensation could not be stopped arbitrarily without a board hearing.

So much for the part of our experience of four years past that should be of use to us when we face a new problem of insurance.

Now to come to the question of sickness insurance proper. What is proposed?

The bill best worth discussing, because it was before our legislature last year, and is likely to come up again in about the same form, is the so-called Doten Bill.

This is really a bill conforming to the draft prepared by the American Association for Labor Legislation. This measure has been introduced in the legislature of a number of the states in practically the same form. The proposals of the "Committee on Social and Industrial Justice of the Progressive National Service" are along the same line.

The Doten Bill proposes a sickness benefit of two-thirds of the wages of the sick worker during his illness; to start with the fourth day of disability; to cover not over 26 weeks in any one year. Medical care is to be furnished him throughout this period, or such part of it as corresponds to his actual time of disability.

Maternity benefits are provided for and a funeral benefit of \$50.00.

The insurance is to be compulsory, and to be financed by contributions of 40% from the em-

ployer; 40% (or less in the poorly paid grades) from the employee; 20% from the State. Control is to be vested in bodies elected from both employees and employers.

The "carriers" of insurance proposed are mutual associations; locals covering a given community, or in the larger centres, corresponding to trade units in the cities.

Participation by commercial insurance companies is not provided for or contemplated.

This is a rough sketch of the provisions.

The general scheme sounds like progress, and it is, perhaps, no part of our function as a profession to pass on the question as to whether it should be enacted into law. Certainly we are not going to oppose it, unless it appear that the medical care, on the excellence of which the benefits to the workman must depend, is going to be badly provided for, unless we are going to run the risk of being forced into inefficient working methods.

As I see it, however, it would be better to have no such insurance than to have it with medical work reduced to the level of lodge practice methods.

Now what of the medical plans?

The American Association for Labor Legislation asked the coöperation of the American Medical Association. The A. M. A., appointed a committee who drafted a report to the Judicial Council, which was published in the *Journal of the American Medical Association* for June 17, 1916.

The third edition of the bill of the American Association for Labor Legislation, published in May, 1916, incorporated some part of this report, and the following are the provisions for the medical administration as there published.

Proper provision for medical care is one of the most important problems in the efficient administration of health insurance. The tentative plan—many of the details of which should be left to regulations to be made by the commission and the medical advisory board—allows each fund or approved society to select the method of administration suitable to local conditions. Where the fund chooses the panel system, any legally qualified physician may join the panel, and the insured workmen shall have free choice among physicians undertaking insurance practice. Since this system may not prove practicable in all districts, freedom should be left to the funds to provide medical care through other methods, such as salaried physicians, among whom there should be reasonable free choice, through physicians responsible for specified districts, or through any other method approved by the commission.

To avoid some of the recognized shortcomings of foreign systems, certain safeguards have been inserted. For instance, the limitation placed upon the number of insured patients whom a physician may treat will go far toward preventing a repetition of the British experience, whereby, under a system of free choice of physician, one-fifth of the doctors are, in many towns, treating one-half the insured population. Moreover, since this limitation is calculated with reference to the probable

number of sick days which a doctor is likely to have in charge, it will prevent extreme cases of overwork, caused by too large numbers of insured patients. In the interests of patients, doctors and funds alike, it is highly desirable to separate the duty of certifying a person as eligible for cash benefit from that of treating him, and for this and for supervisory purposes, a fund may employ a medical officer.

The question of method of payment to physicians is an especially complex one, on which the committee has not reached definite conclusions, although it offers the following points for discussion:

The capitation payment, of so much per person per year, common now in lodge practice, has in it elements which bring about an undue amount of work, and, in turn, forces neglectful, hurried service to the patients. Another plan is that of engaging a salaried physician, similar to the arrangements now made by many railroads. Since no fund could employ many physicians, the limited choice of doctor might be unfavorably regarded by some of the insured persons. The advocates of this system claim that it offers peculiar advantages of selecting the physicians most desirable for this work, and thus of obtaining better service. A third method, payment per visit, is also possible. To the medical profession this method may be preferable because it establishes a quantitative relation between services and remuneration, and to the patient, because it probably secures more careful attention from the doctor, and thus eliminates the chief fault of the capitation system. On the other hand, medical care under this system may put a heavier burden upon the funds administering benefits. A compromise between this and capitation may be made by which a total sum, calculated on the per capita basis, is distributed among physicians in accordance with the services rendered by each. Instead of the elaborate fee schedule common under workmen's compensation, a more simple arrangement is made, whereby a physician is paid pro rata for office and house visits. Although this effectively meets the chief objection to a capitation payment, it may be undesirable to the physician, since the actual payment for each visit may decrease in proportion as work increases. However, the provision of a fixed amount, divided according to services, has administrative advantages, since the total amount paid for medical aid is a fairly constant charge upon each fund.

But whichever system be adopted, one thing is clear: all medical service to the insured will be paid for, including the unremunerated dispensary practice of today. The problem becomes one of deciding which method of arranging for the 100% collections of the future is preferable, in the interests alike of patients, doctors and administrators.

Representation of the medical point of view in the administration is important. This need is met by the presence of a doctor on the Social Insurance Commission and by provision for consultation with representatives of the medical profession on medical matters. This secures a hearing to the medical point of view on both state and local problems.

The necessary supervision may be obtained through medical officers employed by the funds, while matters in dispute may be referred to special committees, both state and local. To these commit-

tees, representing the various interests, power might well be given to remove undesirable practitioners from insurance practice, subject to an appeal to the commission.

**SECT. 7. *Minimum Benefits.*** Every carrier must provide for its insured members as minimum benefits: medical, surgical and nursing attendance; medicines and surgical supplies; cash benefits; maternity benefits; funeral benefit; medical and surgical attendance and medicines for dependent members of their families.

**SECT. 8. *Beginning of Right.*** Insurance, with the exception of maternity benefits, begins with the day of membership. The maternity benefits shall be payable to any woman insured against sickness for at least six months during the year preceding the confinement, or to the wife or widow of any man so insured.

**SECT. 9. *Medical, Surgical and Nursing Attendance.*** All necessary medical, surgical, and nursing attendance and treatment shall be furnished by the carrier from the first day of sickness during the continuance of sickness, but not to exceed 26 weeks of disability in any consecutive twelve months. In case the carrier is unable to furnish the benefit provided for in this section, it must pay the cost of such service actually rendered by competent persons, at a rate approved by the commission.

**SECT. 10. *Medical Service.*** The carriers, subject to the approval of the commission, shall make arrangements for medical, surgical and nursing aid by legally qualified physicians and surgeons, and by nurses or through institutions or associations of physicians, surgeons and nurses. Provision for medical aid shall be made by the carriers by means of either:

1. A panel of physicians, to which all legally qualified physicians shall have the right to belong, and from among whom the patients shall have free choice of physician, subject to the physician's right to refuse patients on grounds specified in regulations made under this act; provided, however, that no physician on the panel shall have more than 500 insured families nor more than 1000 insured individuals;

2. Salaried physicians in the employ of the carriers, among which physicians the insured persons shall have reasonable free choice;

3. District medical officers, engaged for the treatment of insured persons in prescribed areas.

4. Combination of above methods.

**SECT. 11. *Medical Officers.*** Each carrier shall employ medical officers to examine patients who claim cash benefits, to provide a certificate of disability, and to supervise the character of the medical service in the interests of insured patients, physicians and carriers.

**SECT. 12. *Medical and Surgical Supplies.*** Insured persons shall be supplied with all necessary medicines, surgical supplies, dressings, eyeglasses, crutches, and similar appliances prescribed by the physician, not to exceed \$50 in cost in any one year.

SECT. 13. *Hospital Treatment.* Hospital or sanatorium treatment and maintenance shall be furnished, upon the approval of the medical officer of the carrier, instead of all other benefits (except as provided in Section 16), with the consent of the insured member, or that of his family when it is not practicable to obtain his consent. The carrier may demand that such treatment and maintenance be accepted when required by the contagious nature of the disease, or when, in the opinion of its medical officer, such hospital treatment is imperative for the proper treatment of the disease, or for the proper control of the patient. Cash benefit may be discontinued during refusal to submit to hospital treatment. Hospital treatment shall be furnished for the same period as cash benefit. This benefit may be provided in those hospitals with which the funds and societies have made satisfactory financial arrangements, which have met the approval of the Social Insurance Commissioners, or in hospitals erected and maintained by the funds and societies, with the approval of the commission.

SECT. 14. *Arbitration Committee.* All disputes between the insured and physicians, or between funds and physicians concerning medical benefits shall be referred to special committees composed of representatives of the interests concerned, with an impartial chairman appointed by the commission, with an appeal to the commission.

SECT. 15. *Cash Benefit.* A cash benefit shall be paid, beginning with the fourth day of disability on account of illness; it shall equal two-thirds (66 2/3%) of the weekly wages of the insured member. It shall be paid only during continuance of disability, and shall not be paid to the same person for a period of over twenty-six weeks in any consecutive twelve months.

SECT. 16. *Cash Benefit to Dependents.* A cash benefit equal to one-third of the wages of an insured member receiving hospital treatment shall be paid to his family or other dependents while he is in the hospital.

SECT. 17. *Periods of Payment.* Cash benefit shall be paid weekly where possible, and in no case less frequently than semi-monthly.

SECT. 18. *Maternity Benefits.* Maternity benefits shall consist of:

All necessary medical, surgical and obstetrical aid, materials and appliances, which shall be given insured women and the wives of insured men;

A weekly maternity benefit, payable to insured women, equal to the regular sick benefit of the insured, for a period of eight weeks, of which at least six shall be subsequent to delivery, on condition that the beneficiary abstain from gainful employment during period of payment.

SECT. 19. *Funeral Benefit.* The carrier shall pay the actual expenses of the funeral of a deceased insured member, as arranged for by the family or next of kin, or in absence of such by the officers of the fund, up to the amount of \$50. The funeral benefit shall be paid in case of death of a former member while in receipt of cash benefits, or death within six months after discontinuance of

cash benefits because of the exhaustion of the time limit, provided he has not within those six months returned to work.

SECT. 20. *Additional Benefits.* The carriers may grant additional or increased benefits with the consent of the Commission.

SECT. 21. *Extension of Insurance.* When contributions cease on account of unemployment not due to sickness, the insurance shall continue in force for one week for each four weeks of paid-up membership during the preceding 26 weeks.

The first thing that interests us particularly is Section 10, allowing for adoption:

1. Of the panel scheme; a panel including all decently competent physicians in a given district, with right of free choice of physician by patient.

2. Of the limited panel, with "reasonable free choice."

3. District medical officers.

From our point of view, this is pretty broad and the possibilities of Plan 3 (of district officers) becoming honeycombed with politics of the municipal corporation or trade-union brand is considerable.

Plan 2 is something less open to this sort of thing, but might work grave injustice to many physicians in certain communities.

As to Plan 1, it must obviously admit some of the less competent physicians, but it is the plan that commended itself to the committee of the American Medical Association and to the committee of the Massachusetts Medical Society.

It is perfectly evident that if we are to have the open panel, with free choice, we must have supervision and some form of control.

The plan suggested is to have medical officers employed by the funds, to inspect and certify as to rights to benefits; also to suggest consultations, removal to hospitals, etc.

Beyond this there are to be committees (mixed lay and medical committees) to sit on disputes; to prune out the medical panel, if need be (this last is suggested, not incorporated in the text of the draft), from the rulings of which appeal may be taken to the commission.

Also Section 13 provides for hospital care in cases approved by the medical officer of the fund in hospitals with which previous arrangements have been made.

There remains three points for us to discuss in the medical situation:

First, Section 13 calls for a previous arrangement with hospitals under which patients may be cared for. This is open to about the same abuses as the hospital situation today in accident work. It should be provided definitely that such arrangements in order to get the approval of the commission must provide, not only for hospital care but for medical fees as well.

Second, there is no provision for consultants. Provision, in form of a special panel, perhaps, must be made for consultant specialists in the various lines. This has been done abundantly in Germany, and is one reason why the system there has worked so well.

Third, the commission should have the advantage of expert opinion on cases in which the patient's ability to return to duty is disputed. The system of reference of such patients by the Board to impartial physicians for examination and report has proved, in accident cases, to be of service in clearing up obscure cases, and particularly in suggesting procedures to get the patient back to usefulness. It would be a pity not to have some similar safeguard in a sickness insurance law.

Adjudication of such matters by a lay board has proved unsatisfactory in the past, as one might expect. Medical matters should be in medical hands, and there should be an expert medical judgment, above that of the district supervising doctor, obviously.

To sum up, I think we must accept this legislation as bound to come, sooner or later: quite likely sooner.

If the bill of the American Association is to be reported, we should try to make sure that the open panel scheme should be recognized as the best, if not the only scheme; that *proper* hospital contract arrangements should be specified, that provision for a panel of specialist consultants be made; that the commission be enabled to call on impartial examiners in cases in dispute. All these things should go into the bill.

If they cannot be persuaded into it, we should place ourselves in position to have them proposed as amendments. Adjustment of these details by the commission later will hardly do; they will have enough details to settle.

If an attempt is made in amendment of this bill, or in other bills, to open this scheme up to commercial companies, we should place ourselves in position to fight it, not only because it hits us, but because all past experience elsewhere seems to show that the only possible scheme for proper administration of this very complex matter is by central control, through local associations.

Certainly we do not wish to stand in the way of social progress, but it would be better to postpone this matter a little than to have hasty legislation first and hopeless complications afterwards.

**POLIO MYELITIS IN MASSACHUSETTS.**—Three new cases of poliomyelitis were reported in Massachusetts on December 11, one each in Boston, Brookline and Waltham, making a total of twenty-two cases during the first eleven days of the month.

## THE HISTORY AND OPERATION OF THE MASSACHUSETTS WORKINGMEN'S COMPENSATION LAW.\*

By FRANCIS D. DONOGHUE, M.D., BOSTON.

*Medical Adviser, Massachusetts Industrial Accident Board.*

The medical profession, in a discussion of new forms of social, perhaps more properly called welfare, insurance, may well profit by their experiences under the present Workingmen's Compensation Law.

It is a step in the right direction when the medical profession, officially and unofficially, is properly represented at the hearings on social insurance. If the medical profession had been as well represented while compensation hearings were under way, and at the time when rates were being fixed by other commissions, a number of the things which led to dissatisfaction and friction could have been materially modified.

Mr. Justice Crosby of the Supreme Judicial Court of Massachusetts at a meeting of the Berkshire District Medical Society, on June 29, 1916, made a most excellent presentation of the law on workmen's compensation, and its application.

I am sorry that this paper has not been printed for the use of the Medical Society and sincerely hope that it will be, that the legislative committee may have the benefit of it before the legislature meets. The part assigned me at this meeting is to deal with something of the history and operation of the Massachusetts compensation law.

The need of protecting the workman has long been recognized.

Manifestations of this protection are found in the laws regulating the hours of labor; sanitation of factories; child labor legislation; minimum wage; and adequate housing.

Taking cases of mental disease out of the almshouse pauper class and transferring to state institutions where their needs may be studied, is another form of interest.

While the city and the state care for tuberculosis, the efforts for pure food, pure water and pure air are for the protection not only of the worker but for protection of the home from which the future worker must come. All of this legislation, like most moves for progress, was strenuously resisted, but as the greatest good for the greatest number has prevailed, it is but natural that it must continue with education and enlightenment.

Compensation movements, along with demands for other forms of social insurance, had been growing in Germany since 1870, but having been the workmen's compensation act of 1884 but was really only a matter of academic interest in this country.

Although the action of the General Court of

1910 (Ref. Chap. 120, Resolves 1910) in providing for a commission to investigate the subject and to report the draft, led definitely to the passage of the act, public opinion had gradually been growing in this direction for a considerable period.

England in 1880 passed an employers' liability act, and in 1887 the first employers' liability law in the United States was passed by Massachusetts. This act had for its purpose the modification of the principle of fellow servant negligence then operative under the common law. This in no way solved the injustice of dealing with industrial accidents, but indicates that at least the system at that time was not considered satisfactory. Very little was understood in this country with reference to the compensation idea until after the passage of the first compensation act in England in 1897.

The English compensation act of 1897 provided that compensation should be paid by the employer to the injured workman, irrespective of negligence, direct or contributory, and applied to most industries. In 1900 the law was extended to agriculture and in 1906 to practically all persons in service.

Later, certain industrial diseases were given the standing of accidents within the meaning of the law.

In 1904, an attempt was made to pass a compensation act in this state modelled after the compensation law of England. This law failed of passage. Two reasons have been assigned as the cause: first, public opinion had not at that time been sufficiently aroused to the importance of the subject to understand the question thoroughly, and second, the fact that no state other than Maryland had yet taken any action along this line, raised the old fear which always has been existent, and is still when any new form of social legislation is proposed, namely, that Massachusetts industry is in danger of being driven from the field through competition. Each year after the proposal of this law in 1904, an attempt was made to pass a similar measure, but without success.

In 1908 an act was passed which allowed employers to enter into a contract with employees to substitute a voluntary compensation law in place of the legal liability under the employers' law. This contractual compensation method could be made effective after approval by the board of conciliation and arbitration. Contracts of this nature could be effective only for one year, without renewal, so that the system did not work out in practice, and was not utilized.

The real beginning of the present compensation act in Massachusetts is found in the action taken under Chapter 120, Resolves of 1910. It was resolved that "the public good requires a change in the present system of determining the compensation of employees for injuries sustained in industrial ac-

cidents, and that the commonwealth ought to provide different and more suitable relief; . . . . . " A commission was appointed whose term of office was extended by two other acts in 1911, to investigate the subject, and to report a draft of a compensation act, and finally, after exhaustive investigation and hearings, upon the matter, a law was passed which became effective on the first day of July, 1912.

Although the basic principles of this type of legislation may be variously expressed, it is of interest and value to learn the point of view of the investigating commission on the matter. This may best be done by quoting from their report. "The chief object of compensation laws is to provide a definite scale of payments to employees injured in industry. . . . . The Massachusetts law may be briefly characterized as an elective compensation insurance law giving compensation for all injuries arising out of employment irrespective of negligence except those due to the serious and wilful misconduct of the injured employee. The basic principle of the act is that the cost of injuries incidental to modern industry should be treated as part of the cost of production. The act was framed with that end in view. . . . . The law will operate to prevent injuries."

With reference to the administration of the law the same report states in another place as follows: "The commission was of the opinion that the controversies under the act should not be dealt with in the ordinary courts. . . . . the commission believed that it was necessary to have an administrative board intrusted with the execution of the law. . . . it was thought unwise to allow the law to be administered by the judges of the courts, as the details of administration would differ widely in different courts. This difficulty has been experienced in England. The Industrial Accident Board is designed to provide a medium for the settlement of controversies which will act uniformly throughout the Commonwealth."

"The loss arising from the present system of determination of controversies, with its great waste of money in connection with litigation, will be materially reduced. The difficulty under the new law will not be so much in the determination of matters of legal liability as in the ascertainment of the physical incapacity of the injured man."

"The controversies under the act will relate largely to the extent and duration of the injury. The successful administration of the act requires the assistance of skillful physicians and surgeons of the highest integrity. This phase of the situation has occasioned difficulty in other countries. The details of this subject must be determined by the Industrial Accident Board as they arise in actual practice. The emphasis will be laid *not*, as heretofore, *on the lawyer, but on the doctor.*" [Italics are mine.]

"In addition to its duties with relation to

controversies under the act, the Industrial Accident Board has other important functions. . . . . The statistics gathered by it will be of great value, especially in determining the physical cause of the injury. It is evident that the cost of the new law will depend largely on the success of employers in preventing accidents."

"The Industrial Accident Board can render invaluable service to employers by co-operating with them in the practical study of accident prevention. It is the Board's duty, also, to supervise the rules for accident prevention, established by the Massachusetts Employees Insurance Association. This branch of the Board's duties will be of great public consequence. . . . . Another important function of the Board will be the supervision of agreements for compensation. It is believed that a large number of cases will be disposed of in this manner, and the Board must be careful to see that the rights of the parties are safeguarded." (The report of the Commission has been quoted at length for the purpose of showing the point of view from which the work of drafting the compensation act was developed.)

The next step is to trace in a general way the history of the operation of the law in practice, and to indicate some of the changes which have been made through subsequent legislation. As originally passed, the compensation act provided for a board of five members and a secretary. Clerical assistance and other operating expenses were provided for by an appropriation of \$10,000, an amount really insufficient for carrying on the vast amount of work for one month. No provision was made for a medical adviser, although admittedly a great part of the successful administration of the act was dependent on the determination of questions having to do with the physical incapacity of the employee, and the relation between a condition of disability and an actual or alleged industrial injury.

No provision was made for a corps of inspectors or investigators for the work of investigating the causes and prevention of injuries, and facts to assist the Board in enforcing the speedy settlement of cases. In other ways, the original organization might have been better equipped for carrying on and developing the work along the lines of thought which really underlie the compensation act. Some of these deficiencies in the first law were later adjusted, as experience developed the need.

A brief review of the accident experience in the state since the act went into effect is advisable as showing the extent of the problem. In the first four years of the act, approximately 417,000 injuries have been reported to the Board. About 11 million dollars have been paid or are to be paid on account of the injuries which arose in this period. Of this amount 22 per cent. has been paid as medical benefits, or about \$2,420,000.00. In the first year of the

act, approximately 81 per cent. of the injured employees were insured under the act; the number now insured runs between 90 and 95 per cent. In the first year of the act the average number of reports received per month was about 7,500; in the second year the monthly average was 8,200; in the third year the average was 7,100; in the fourth year the average was 11,475; and for the first quarter of the fifth year the monthly average is 14,000. Roughly speaking, at least sixty per cent. of the cases require some sort of medical attention.

Around 20 per cent. of the cases have a disability sufficient to entitle them to compensation. The cost of non-fatal cases expressed in terms of compensation is more than the cost of fatal cases and medical attention in all cases combined. In other words, more than half of the money expended in benefits goes to the payment of compensation to injured employees while undergoing the process of repair, or to those whose condition is beyond repair under the present condition.

In the course of the operation of the act, in addition to specific amendments made there have been decisions under the act, which have made definite the status of cases not easily determined to be within the scope of the law. The most important example of this is found in the application of the law to cases of occupational diseases, developed by the Hurle and Johnson cases. (Ref. Bulletin of Ind. Ac. Bd.)

The original act provided, as benefits, medical attention for the first two weeks after the injury, and the payment of compensation at the rate of fifty per cent. of the average weekly wages. The act was later amended (in effect October 1, 1914) so that in unusual cases medical attention might be provided beyond the period of two weeks; and the rate of compensation was increased to two thirds of the average weekly wages, and the period of benefits in fatal cases was increased from 300 weeks to 500 weeks. On the first of January, 1917, another amendment will be in effect, providing a ten-day waiting period, instead of the period of two weeks, so that the injured employee will soon be entitled to his first weekly payment on the 17th day after the injury, instead of waiting until the end of the third week.

There is also a provision of law that compensation shall be paid, in spite of appeal, unless otherwise ordered under Chapter 132, Acts of 1915, and an amendment, Section 4, Part 11, as amended by Chapter 90, General Acts of 1916, that when compensation shall have begun, it shall not be discontinued except by the written assent of the employee or the approval of the Board or a member thereof. In effect Jan. 1, 1917.

Probably the greatest factor in the satisfactory carrying out of the Massachusetts law has been its intelligent development along medical lines.

The old form of controversy, by presenting witnesses for and against the claimant, so that the man's rights depended upon the weight of the evidence presented at a hearing, has been materially modified by the naming of so-called impartial physicians. It was found that the malingering or fakir in Massachusetts was almost an unknown quantity, and that when a man came to the Board with a claim, 99 times out of 100 it was a just claim. The question then came on selecting doctors to examine these claimants, with the idea that a specialist in restoration of function was needed rather than a doctor who would say, "yes, the man is disabled," or "no, the man is not disabled." In the early days of the act, the insurance companies did not avail themselves of the impartial examiner, because examiners were not picked out along special lines. With the advent of the medical adviser, taking office in December, 1914, there was a great increase in the amount of work the insurance company put up to the medical adviser for aid in solving.

It is, of course, manifestly impossible for the medical adviser to examine all disputed cases, or even a small portion of them, and if it were physically possible, it would be an extremely unwise, not to say dangerous, thing to have any man placed in the position of examining accident cases in conference, again to express his opinion at a formal hearing, and then to insist to the full board that his opinion was the end of the medical law and must be accepted. The great success of the Accident Board has come from the utilization of the best medical brains in the Commonwealth. The medical profession should consider it an honor to serve as an impartial examiner, and men should be willing to make some sacrifice fully to preserve this feature of the law.

It has been, and is, to the credit of the medical profession that they are loath to discuss in terms of dollars and cents their service to the individual or to the community, but the changing position of the medical profession, brought about by the increase and concentration of population, by the ever-widening influence of state medicine, the loosening of the ties between the physician and the patient, the gradual submergence of the family physician,—all bring us face to face with need of change and readjustment to meet modern conditions.

A well-paid medical service will produce the best results.

Money is needed for the proper maintenance of the doctor's family; money is needed for the proper maintenance of equipment, books and magazines; and money is needed to provide the opportunity of keeping abreast of progress by intercourse with doctors at a distance by medical society attendance.

If we consider the law of 1912 from the doctors' standpoint, the small consideration ac-

corded to the medical profession is extremely striking.

The law consisted of 5 parts and 76 sections.

Part I of the law consists of 5 sections under modification of remedies.

Part II consists of 23 sections, of which Section 5 is devoted to the medical profession, and which reads as follows:

"During the first two weeks after the injury, the association shall furnish reasonable medical and hospital services and medicines when they are needed."

Section 19, authorizing an examination of the injured man by a physician or a surgeon sent by the association or subscriber, reads as follows:

"After an employee has received an injury, and from time to time thereafter during the continuance of his disability, he shall, if so requested by the association or subscriber, submit himself to an examination by a physician or surgeon authorized to practice medicine under the laws of the Commonwealth, furnished and paid for by the association or subscriber.

"The employee shall have the right to have a physician, provided and paid for by himself, present at the examination. If he refuses to submit himself for the examination, or in any way obstructs the same, his right to compensation shall be suspended, and his compensation during the period of suspension may be forfeited."

Part III consists of 18 sections, and has one section relating to physicians—Section 8—which reads as follows:

"The Industrial Accident Board or any member thereof may appoint a duly qualified impartial physician to examine the injured employee and to report. The fee for this service shall be five dollars and travelling expenses, but the Board may allow additional reasonable amounts in extraordinary cases."

Part IV consists of 24 sections and contains nothing relating to doctors.

Part V consists of 6 sections, miscellaneous provisions, largely of definitions.

In addition to that, Chapter 311 authorizes mutual insurance companies to transact the business of employers' liability insurance, so-called, and Chapter 666, Acts of 1912, is an act relative to the insurance of compensation to employees for personal injuries received in the course of their employment.

The rules formulated by the Board under this law are eight, none of which have to do with the rights of the doctor. Hardly a word of the rights of the individual medical practitioner.

Under Section 13, Part III, "fees of attorneys and physicians, for services under this act, shall be subject to the approval of the Industrial Accident Board." Under this section the Board made a ruling that fees should not be charged an injured party whose employer was

insured, larger than the injured party would be charged were he not insured.

As this ruling was extremely unsatisfactory, and as other medical administrative problems annoyed the Board, they were obliged finally to turn to the medical profession for help, and after a meeting at the State House (Ref. Bulletin No. 4, Industrial Accident Board, April, 1913) appointed, at the recommendation of the Mass. Medical Society, two members, Mass. Homeopathic Society, two members, and three members were named by the Board; Dr. F. J. Cotton of Boston and Dr. F. W. Anthony of Haverhill, named by the Mass. Medical Society; Dr. S. H. Calderwood of Boston and Dr. S. E. Fletcher of Chicopee, named by the Mass. Homeopathic Society; Dr. W. H. Ruddick of South Boston, Dr. F. E. Allard and myself were appointed from the standpoint of the Board. This committee considered the matter in a comprehensive way and arrived at certain conclusions after a study of a large number of doctors' bills, and hospital and nursing disputes.

The work of this committee, while not fully understood, led to much of the constructive legislation which followed and to this committee the medical profession should ever be grateful.

I will briefly review their recommendations and the underlying reasons for the recommendations, because further constructive work is possible. (Ref. Bulletin No. 6, Industrial Accident Board, Nov., 1913.)

"First.—That a permanent advisory medical committee is necessary."

To this committee the Industrial Accident Board can turn for aid in establishing principles from the medical standpoint. It is not designed to do the work of the Industrial Accident Board or its members, and it is not to sit for continuous judgment upon details, but to supply the basis upon which the Accident Board may apply the law.

"Second.—That we consider it inexpedient to have a medical man as a member of the Industrial Accident Board."

This was to be taken only as of the time at which the recommendation was made. It was left open for future experience and development to say whether or not medical interests would be properly conserved by an entire board of lay men.

"Third.—That the Industrial Accident Board should have a consulting surgeon upon whom should fall the duty of detail work in preparation of matters to be laid before the advisory committee. Matters in dispute regarding services and fees of physicians should be referred to this committee for recommendation."

This was followed by enactment of the law providing for a medical advisor who acts as a consultant with the medical advisory committee, with hospital committees and with individual doctors in endeavoring to secure fair treatment along the lines recommended by the med-

ical advisory board, and to advise the board or any member when called upon.

"Fourth.—That insurance companies be requested to provide suitable blanks for notifications as well as specifications of services rendered by physicians."

A large part of the friction between doctors and insurance companies in regard to bills arose from the fact that the insurance companies did not know the doctor's side of it, and while it led to a little more work on the part of the doctor, it removed a large amount of friction.

"Fifth.—That industrial insurance companies be encouraged to allow all reputable physicians to render services in industrial accidents, provided they are willing to render such services upon a reasonable basis."

This was acceptable to all but a few insurance companies and all insurance companies in some measure have accepted the spirit of this in whole or in part.

The Peccot decision has changed the attitude of some companies. (Ref. Bulletin Ind. Ac. Bd.)

"Sixth.—That the Accident Board should make arrangements with which the insurance companies should cooperate; that any physician whose bill is in dispute may appear before a representative of the Accident Board within a reasonable distance of his home."

Not only was this recommendation adopted, but the law was so amended that it gave the physician the right to ask for a hearing on his bill independent of the employee for whom the service was rendered. Under the first law a doctor had no right to ask for a hearing unless the employee asked for it for the doctor.

"Seventh.—That the Accident Board shall provide for medical referees by districts."

This section is capable of further elaboration, and while the essence of it is preserved in the naming of impartial doctors, the impartial doctor has not been utilized along the line of the medical referee under the English law or as a referee sitting with a committee of arbitration.

"Eighth.—That fees paid by the companies should not be less than the average minimum fee in the locality in which the service is rendered."

This refers to fees paid to doctors, not to contracts between doctors and the insurance companies. This took into account that many medical and surgical fee tables, established by local medical societies, had perhaps been based upon the average income of the so-called better classes and were not generally applicable to working men, who form such a large part of the free hospital and dispensary service or who turn to fraternal organizations or hospital associations for low cost service.

"Ninth.—That charges up to \$50 for major operations are not excessive."

This did not fix a maximum, but made possible other payments based upon circumstances.

"Tenth.—That physicians appearing at hearings before the Board shall receive the compensation as provided for under section 8, Part III, of the act."

This was designed to pay a physician a little higher rate than was provided in Section 3, Part III; the fee for attending as a witness before the Industrial Accident Board shall be one dollar and fifty cents a day; for attending before an arbitration committee, fifty cents a day; in both cases five cents a mile for travel out and home."

"Eleventh.—That services rendered by lodge physicians be paid for, provided it is not inconsistent with the rules of the order."

The status of the lodge physician is a very difficult one upon which to pass, but as the choice of lodge physicians, to which a member is obliged to go, is somewhat similar to the insurance company providing a man to whom the employee might be obliged to go, the committee left the matter open.

"Twelfth.—That specialists, established and recognized by the profession as such, may receive special rates for their work, provided the case requires special skill."

This requires no comment.

"Thirteen.—That the ruling previously made by the Accident Board that 'fees should not be charged an injured party whose employer was insured larger than the injured party would be charged were he not insured,' should be interpreted to mean that in a given accident the fee paid by the insurance companies for services should not be less than the average minimum fee for similar services in the locality in which said services are rendered."

Was construed by the Accident Board in conjunction with recommendation eight.

All of these recommendations have as far as possible been carried out by the Industrial Accident Board, and form the basis of substantially all rulings on medical matters except as to hospitals. A special hospital committee made recommendations as to hospital care, and hospital charges, somewhat modified by a second hospital committee two years later. It is very evident that in the relation of general practitioners to hospital cases, the hospital to the workman, and the staff to the hospital, there is no uniformity, and changes are necessary.

It is impossible in the twenty minutes allotted to cover thoroughly even the essentials of the compensation law.

In previous articles, *The Medical Aspects of the Workingmen's Compensation Act*, in the *BOSTON MEDICAL AND SURGICAL JOURNAL* of Sept. 21, 1916, and *The Restoration of the Working Capacity of Injured Employees*, in the *BOSTON MEDICAL AND SURGICAL JOURNAL* of Oct. 7, 1916, I have covered other aspects of this subject.

There are two other phases which need to be covered:

One concerning specific payments for specific injuries. One is about the duty of the doctor in filing a notice of injury to protect both the patient and himself and how the doctor could materially aid both the workman and the compensation board by follow-up observation in cases which may be entitled to specific compensation.

These I hope to be able to cover in a future paper.

The entire machinery of the Board has but one aim, and that is so to administer the Workingmen's Compensation Act as to mete out justice to all, bearing in mind the fact that the highest court in our Commonwealth has stated that the law is a humane one; that it is to be interpreted broadly and liberally; and that the benefits provided thereby must not be made illusory, but rather that the relief granted must be substantial.

All of the human misery which springs from industrial accidents should be eliminated, if possible; and when all of us have every incentive, from the point of view of cost and human welfare, no stone should be left unturned to bring about the end to which all roads lead,—safety to life and limb and the conservation and rehabilitation of the victims of industrial accidents.

#### WORKINGMEN'S COMPENSATION FOR ACCIDENT AND SICKNESS, FROM THE POINT OF VIEW OF THE GENERAL PRACTITIONER.\*

By W. H. MERRILL, M.D., LAWRENCE, MASS.

*Mr. President, Fellows of the Massachusetts Medical Society:*

THE invitation to meet with you and hear the discussion of subjects so vital to the profession is a highly prized one. I assume the invitation came to me because I live in one of the four or five largest industrial communities in the State,—communities where the profession is most profoundly affected by these socio-medical laws, and proposed laws. Nearly one-half of the people in Lawrence are subject to the operation of the Compensation Act. The desire you manifest to hear all sides of this problem which, as physicians, enters but little into your own work, is a pleasing token of your catholic interest in all things that affect the medical profession.

The announcement that I would attempt to present the general practitioner's views on these questions may lead to some misunderstanding, for I have done no general practice for twenty years. If I fail to get the viewpoint of the general practitioner, I hope he will not

\* Read at a meeting of the Suffolk District Medical Society, October 25, 1916.

be criticized for the things I say which do not represent his thought, and that others will present the points he considers important, which I fail to.

There are two reasons why I am willing to attempt to voice the views of 90% of the members of the Massachusetts Medical Society. First, my admiration and respect for the general practitioner as I know him. My debt to the physicians who specialize is great, and I hope to be always very grateful to them for having placed their splendid skill so freely and sympathetically at the disposal of my family and myself; but to the physician and friend, the general practitioner, who has cared for us in illness and in trouble, even a deeper sense of gratitude is felt. He may guess at times or often, but the shrewdness of his guesses on the points most vital to the comfort and life of his patient is a perpetual source of surprise and admiration to me. The relations which beget this feeling may not exist in large cities, but they are a very real part of life in the small cities and towns, and if not present in large places, their absence is a part of the price paid for other advantages. The second reason is due to the chance which made me chairman of the Essex North District Medical Society at the time the Compensation Act became effective. The membership of Essex North is composed of more than 90% general practitioners, and it seemed to me the duty of its officers to get, and attempt to represent, their views.

In appraising the conditions arising under the law it should be borne distinctly in mind that the employer and the insurance company are two distinct factors. Some misunderstanding is due to lack of appreciation of this distinct separation. The insurance company acts as the financial agent of the employer, but in the wider important relations in the field of humanity the insurance company does not act, and cannot be expected to act, as the employer would. It is not possible for groups of men, organized in a foreign country for the purpose of getting money, to have the same interest in the workman of Massachusetts as his employer has. When the compensation law became effective four years ago, a considerable number of surgeons, who were engaged in a movement to elevate the standard of surgery, were apparently hopeful that the centralized power, lodged in the hands of the insurance companies, would be used in a way to aid their movement. That this hope has proved elusive is evident. What is the evidence?

1. Not a single hospital in the state has been built and equipped by an insurance company. The movement for plant hospitals and plant nurses was being developed when the law was passed, and it would be difficult to prove that this movement has developed faster than it would have done had there been no law; and I think it a reasonable conclusion that in many

instances the employer gladly turned the whole matter over to the insurance companies, to the detriment of the employee, when under former conditions he would have felt compelled to follow with interest the development of industrial hygiene. I wish my command of the English language was better, that I might make this distinction between employer and insurance company distinct and not to be forgotten, for I conceive it to be a vital part of the problem. Allow me to cite illustrations of this and the different attitude of the employer and insurance company. One of the corporations in Lawrence employing 6000 to 7000 people, had for years paid about \$4000 to six or seven physicians in its neighborhood for caring for its injured employees. They paid competent men a fair fee to care for the employee until that employee was able to return to work. When the matter fell into the hands of an insurance company, they contracted with a young man, whose need apparently was extreme, to do all of this work for \$900. This contract existed two or more years, to the dissatisfaction of the employees, to the physician himself, who said he could not afford to do the work for \$900, and, I understand, to the management of the industry also.

Another corporation, with 5000 employees, formerly sent its poorer-paid, help to the out-patient department of the hospital, but never refused to pay reasonable bills for those who did not go to the hospital; and its better paid employees were usually cared for by competent men as private patients during all of the period of disability. The insurance company now sends all the employees to the out-patient department. At least 20,000 of the 35,000 or more employees in Lawrence are sent to the out-patient department of the hospital, and the insurance companies are generally refusing to pay the family physician for caring for the few who refuse to go to the hospital.

This difference in attitude by employers and insurance companies toward the medical problem in the act was well illustrated in Newburyport. When the condition became understood in 1912, the Newburyport Medical Club asked the employers of labor if they believed it right for their employees to choose their own medical attendant. Ninety per cent. replied that they did, and agreed not to insure in a company which would not accord that freedom of choice.

It is urged by those who profit by the present law that it is necessary to lodge the power over the bodies and wills of the workmen in the insurance company, to protect the workmen against maltreatment and the insurance companies from extortion. If all our citizens were as loyal to common-sense medicine as is the group covered by this act there would be no necessity to protect the public from Occidental cults or Chinese herb doctors. The question is more concrete than that, however. I believe there are those here, conversant with the situa-

tion in some of the industrial communities, who will readily agree that many of the selections made by the insurance companies have been deplorable, and the ill results are much more widespread when one less competent man is hired to care for five thousand employees than if such a man gets only a small part of the work by competition. These citizens covered by the act have common sense and a desire to develop it, and it is very much more to the credit and profit of our country if all possible means are used to inform them of the best agencies of which they can avail themselves, than to compel them to be automatons in such important matters. No one desires the abolition of plant hospitals and nurses, and few, if any, believe the employee so lacking in sense to refuse to avail himself of really good service when offered without compulsion.

The framers of the act and the legislators who enacted it took full cognizance of the money-getting proclivities of the medical profession, and created a board with full power to pass upon the reasonableness of all charges. It has not been pointed out what more effective way could be devised. Through the interpretation of the law and the refusing to pay fees only to men hired by them, the control over this important matter has been grasped by private corporations and wholly removed from the hands of the State. It is not credible that the legislators understood what they were doing.

While the members of the profession are accused of being mercenary and commercial, all their suggestions that there is a civic principle involved is termed sentiment, and all the argument against an amendment met by the objection that it would cost more.

Whenever the insurance companies attempt to contract with a physician for services or to settle a bill, they talk "industrial rates." It is proper for us to examine for a minute the net results of their rates for services. The last report of the Commissioner of Insurance for the year ending June 30, 1916, states that the Rate-Making Bureau, composed of a representative of each of the companies and one from the State Department of Insurance, agreed upon 17½% as the rate of premium to be charged for writing compensation policies. This 17½% includes no office or any overhead expense. This same report gives the net premiums of the stock companies for the last year as, in round numbers, \$5,600,000; 17½% of this is \$980,000. Recalling that the removal of the employers' safeguard under the common law has practically compelled the employers to be insured, it is evident that this sum of \$980,000 has been absorbed by the stock companies in getting the business away from each other. The total benefits paid under the law was \$3,500,000. The experience of the year before (figures for this year not yet compiled) was 22% of total benefit absorbed in medical attendance, including hospitals and all

supplies. Accepting this figure as approximately correct for last year, it would produce \$770,000 paid for all forms of medical attendance,—\$210,000 less than was paid as agents' profits.

While the Accident Board and its Advisory Committee was trying to straighten out the tangle of unpaid bills four years ago, a member of the Accident Board facetiously remarked that "This is not a doctor's bill." This the doctors readily admit, and they now have an idea whose bill it really is. Mention of the Advisory Committee of physicians who aided the Accident Board during the first turbulent months, recalls the debt the profession owes to these Fellows of the Homeopathic and Massachusetts Medical Societies, for the hard, trying work which they performed. While all may not have agreed that palliative treatment was the one indicated, there was no doubt of the great relief their work afforded the suffering profession.

Proponents of present conditions also say, "A broad view should be taken of the matter"—that we should think only of John Smith's cut finger. It is very possible John's cut finger has been magnified by surgical inclination and other reasons, until it obscures altogether more of the field of vision than it would in its natural size. It is said sentiment should not be admitted as a factor in the problem. May I tell you a story,—a true story of the working of this act,—in which it is shown to strike at one of the most important sentiments which we all possess? The younger brother of one of the physicians of Lawrence had a finger injured while employed in one of the mills. When he reported the injury to the boss, he was told to go to the out-patient department of the hospital for treatment. The young man objected, saying he did not want to go to the out-patient department anyway, and did wish to go to his brother. He was told to go to the out-patient department or go to the office and get his time, which meant his discharge. Confronted with the dilemma of losing his job or going to the out-patient department, he went to the clinic—and his brother who happened to be on duty, treated him. Money consideration did not enter into this transaction; it was the sentiment which impels every man to enforce, if possible, the right to his own body.

If the workmen and the physicians in the industrial communities believe some of the medical provisions of the Compensation Act to be wrong, I submit that they will be guilty of a lack of civic spirit and of cowardice; if they do not attempt to register that belief in the most effective manner possible.

The commercializing of the profession has been a frequent topic of discussion at all times. It is so true as to be hardly questioned that nothing has occurred to commercialize the profession as the application of this law. Section of the Code of Ethics of the State Society con-

tains the following paragraph: "Physicians should take no steps with a view, directly or indirectly, to direct to themselves the patients or practice of others." If the State Society is to accept the present conditions, in which members contract to have the patients of their confrères sent to their offices under duress, it would seem only consistent with common honesty officially to expunge the code of this statement.

#### HEALTH INSURANCE.

A euphonious title chosen for its psychological effect. The underlying idea of the medical provision is stated to be: first, preventive medicine; second, the caring for the ill more effectively; and, third, at less expense.

It is stated that a contribution by the employer will incite him to consider ways of preventing illness. This is probably true if the trouble of doing this does not seem more expensive than the illness. It is a safe guess that at the first meeting of the Board of Directors after organization is perfected, and the medical phase of the act is to be provided for, the question before the house will be how doctors be procured cheapest. For a long time this will be the point at which economy methods will be applied. The beginning of efficiency methods, cost methods, at this point will have a positively unfavorable effect upon both of the more important factors. A limitation of the number of men employed, to the point of least expense, will render attention to preventive medicine unlikely. The most desirable physicians will refuse to have anything to do with it, if there is a small panel, and the gulf between the quality of medical services the well-to-do and the poor receive will be apparent as never before. Good medical service cannot be bought cheap any more than good service of other kinds. It is my belief that a further reduction of the income of the physicians in the industrial centres will certainly reduce the efficiency of the service. A reduction of fee for amount of work done will fall heaviest on those men who observe more carefully the admonition of the ethics of our profession. Let me reiterate. It is not fear for the financial welfare of any group of men that gives rise to this anxiety about fees, but a desire that fees should remain at least at a point which will insure the public good medical service. There is also a civic side to this matter and that is, the value to any community with a representative form of government of an independent body of intelligent men.

The report of the committee of the American Medical Association is so exhaustive and suggestive there seems nothing more to desire but a knowledge of just how such laws work in England in time of peace and how adaptable they are to the needs of a real republic. What will the country gain and what will it lose? As with all new things, it is incumbent upon this

proposed innovation to demonstrate its value in theory, and in practice where it has been tried. It is well that new methods should be thus examined for they often are intended to displace methods evolved by civilization at much cost. It is the duty of the profession to exercise that first law of nature, self-preservation, so far as to attempt to shape the medical details of legislation that the profession's usefulness may not be curtailed.

#### WORKINGMEN'S COMPENSATION FOR ACCIDENT AND SICKNESS, FROM THE POINT OF VIEW OF ORGANIZED LABOR.\*

BY JOHN P. MEADE, BROCKTON, MASS.,

*Chairman, Legislative Committee, Massachusetts State Branch, American Federation of Labor.*

THE Workingmen's Compensation Act of Massachusetts has now passed the experimental stage. Each fundamental provision of this important legislation has been tried for more than four years in the field of actual experience. We are just beginning to realize its value, not only to the individual worker, but, what is even more important, to the homes of the Commonwealth. Through its application in very many instances, dependents of the victims of industrial injury have been saved from becoming charges upon the public, and spared from the effects of destitution and want. We have here in the operation of this law the foremost social improvement of our time.

In the light of past experience, what can be done to relieve the worker in our mills and factories who suffer the pain and torture of industrial accident? This problem is just as acute and vital as it ever was, and its only answer is that the highest form of medical service and the best kind of surgical treatment should be placed at the disposal of the injured workman. Any effort or attempt to cheapen this treatment and service will meet with the most emphatic protest by the working people of our State. The worker who engages in the hazardous occupations, whose life is jeopardized daily in the interest of society, should not be sacrificed on the altar of selfishness and greed. His right to adequate care and assistance to recover at the earliest possible moment from the effects of accident should be freely recognized. This right should not be denied him by any attempt to contract medical treatment out to the lowest bidder. There are, among others, two important principles of the Compensation Act that must concern the medical profession, as represented by the Suffolk District Medical Society.

\* A compilation of articles published in the *Medical Society Bulletin*, October, 1914.

I refer to the sections of the act that pertain to the medical adviser of the Board, and the duty of impartial physicians.

How important the duty of medical adviser is! His judgment must be as accurate as the human mind can make it. He must be absolutely above any selfish consideration. His opinion in the final analysis, in the very difficult cases which deal with the medical problems arising therein, is of tremendous importance to the welfare of the working people and the correct administration of the act. What labor asks in such an official is justice. We do not want, neither do we seek, that which does not belong to us. We have no complaint in this respect now. Indeed, the courage and ability of the present medical adviser is so well known throughout the State, that the layman at least points to this fact with the strong conviction that it has resulted in building up confidence among the laboring people in the administration of the compensation law.

The work of the impartial physician is of great importance in the proper operation of the act. His written opinion is now admissible as evidence before arbitration committees in case of controversy. The impartial physician should be selected with great care. His credentials for this duty should be marked by experience and the highest ability.

In many instances a knowledge of the conditions under which the workman recovering from an injury is to be employed should constitute the basis for a liberal prognosis. Especially is this true in cases of amputated phalanges among workmen in the shoe industry who are engaged in cutting sole leather. Men employed in this occupation handle a large die, and frequently must use the injured digit to guide its operation. Unless these considerations are given their adequate value in the determination of when the workman injured in such employment is restored to his normal working capacity, an injustice is sure to be inflicted upon him. Such instances are prolific sources of disagreement between the insurer and the victim of industrial accident, and forces the workman to establish his rights through arbitration proceedings.

To my mind, every physician should become familiar with the general principles of the act. Every doctor should at least be qualified to advise those who suffer from injuries arising out of and in the course of their employment, as to their rights under the Workingmen's Compensation Act. If such a course were followed, the justice of claims, now so frequently in dispute, could more easily be established. Nearly 800,000 workmen are now within the scope of the Massachusetts act, and are vitally concerned with its administration. The Massachusetts Branch of the American Federation of Labor, representing the organized workmen of this Commonwealth, at its recent convention in Spring-

field, devoted nearly two days to discussing various phases of the compensation law, and the relation of injured workmen thereto.

That insurers should provide the injured worker with medical treatment during the entire period of incapacity, and that the victim of industrial accident should be given the right of choosing his own physician, were declarations which met with unanimous approval by this gathering.

Touching, as it does, the medical profession through many different points of contact, it seems to me quite appropriate to urge greater interest in the greatest piece of social legislation of modern times.

This work would be of most practical value, and although I am aware that no group of professional men in the community give freely of their talent and skill more than do the physicians, yet an intelligent interest by the medical profession in the operation of the act could only result in its more efficient administration.

#### THE ADMINISTRATION OF THE WORKINGMEN'S COMPENSATION ACT BY THE CITY OF CAMBRIDGE, MASSACHUSETTS.\*

BY HERBERT J. CRONIN, M.D., CAMBRIDGE, MASS.

THE city of Cambridge at the city election on March 10, 1914, accepted the provisions of the Workingmen's Compensation Act<sup>1</sup> for its laborers, workmen, and mechanics as allowed by Chapter 807 of the Acts of 1913 for Massachusetts. This act<sup>2</sup> grants the same compensation provided by the general compensation act to certain public employees only—the laborers, workmen, and mechanics. The clerical force, firemen, policemen, superintendents, and city officials are not included under its provisions; if injured, they still have their rights to sue at common law.

A city either may operate its own insurance under the jurisdiction and supervision of the Industrial Accident Board, just as the regular insurance companies, or it may give the insurance to a private insurance company. The city of Cambridge chose to operate its own insurance.

#### INSURANCE DEPARTMENT OF THE CITY OF CAMBRIDGE.

The chief of the administrative department of the workmen's compensation insurance for the city is the mayor. He has designated his secretary to act as the agent prescribed by law.<sup>3</sup> This agent is held responsible by the Industrial

\* Read before the Middlesex South District Medical Society, October 11, 1916.

Accident Board for the proper administration of the act. He must investigate claims, furnish the benefits due, and advise the Board of all agreements or settlements made. The agent's office is an appointive position by the mayor, not subject to the confirmation of the council. The salary is \$500 a year. Legal questions are referred by the agent to the city solicitor, who is paid a yearly salary to administer all the legal affairs of the city. Thus far but few compensation problems have been referred to the solicitor.

The medical department is in charge of a physician appointed by the mayor without the confirmation of the council, and requested by him to furnish the medical services required by law<sup>4</sup> to the injured employees. The compensation physician is paid by the case, and the same fee is charged as in the treatment of a similar type case in private practice. The mayor demands that the best medical service obtainable be given to the employees, and urges that every medical aid which will decrease the suffering or shorten the incapacity of the injured men be employed. Rather than merely to follow the prescribed provisions of the law, he suggests that the broad, humanitarian principles, which animated the creators of the act, be cultivated in its administration in Cambridge.

#### DISPOSAL OF CLAIMS BEFORE THE ACT.

Before the acceptance of the provisions of the Workmen's Compensation Act, the method of adjusting claims of injured employees was inadequate and unfair. Men injured in the service of the city and desiring compensation were compelled to place a petition before the Committee on Claims of the City Government, begging for a continuance of pay. This committee would consider the claim, would have a hearing, and could, with the approval of the mayor, award the continuance of pay during the man's incapacity. The men had no definite rights. If it could be proved that the man was negligent, that the neglect of a fellow employee caused the accident, or if it was presumed that the employee assumed the risk of working in a dangerous place, consideration of the claim might be refused. Sympathy might persuade or influence the committee to award claims, regardless of the true conditions in the case. Now all claims for injury must be settled on an equal basis, determined by law.

#### PRESENT METHOD OF PAYING COMPENSATION.

An injured employee is entitled under the Workmen's Compensation Act to full medical service for the first two weeks, but no wages. At the end of that period, he receives two-thirds of his weekly wages, but not more than ten nor less than four dollars a week for the period of his incapacity. Compensation on the above basis, for 500 weeks, but not more than \$1000, is paid

for total incapacity or death. Every laborer, workman, or mechanic, in the employ of the city is eligible to the benefits, unless it is proved that the injury was received by reason of serious or wilful misconduct.<sup>5</sup>

The money for compensation is paid out of the payroll of the department in which the man is employed. There is no general appropriation in the yearly budget for the purposes of workmen's compensation. When there are definite appropriations in the budget for specified work, claims for compensation for injuries received on the work are paid out of that particular money. Because of the many hazardous occupations, the street, sewer, and water departments have suffered most heavily from compensation claims.

The death claims are paid in weekly installments to the dependents, from the department's payroll in which the employee worked. Although the law allows a lump sum settlement<sup>6</sup> to the dependents in certain cases after six months, there has been no departure from the weekly payments. Such payments would be difficult in this city because they would drain the appropriations of the department in which they occurred, and might embarrass its operations for that year. Provisions for such claims would have to be made in the budget at the beginning of the year.

#### AN INSURANCE FUND FOR WORKMEN'S COMPENSATION PURPOSES.

A special fund in the city might be created to cover claims for compensation. At present a few departments pay most of the compensation. To equalize conditions, every department could contribute a small yearly premium into a reserve fund devoted to compensation purposes. The premium could be regulated by the number of employees insured and the hazards of the department. As the fund would increase in size yearly, it would soon form a strong reserve fund. Then, in case of a serious accident, resulting in death or long periods of incapacity, the compensation could be paid out of that fund without interfering with the operations of the department. Immediate settlement of all claims would be assured, and a substantial lump sum payment could be allowed the dependents.

The objections to such a fund are that the city has a general reserve fund; that departments which have no accidents would be assessed for those that did; and that the city is always able to borrow money. Yet the present system is not satisfactory. There are too many opportunities for error when each department settles its own claims.

To improve these conditions, there should be taken from the tax levy an adequate sum sufficient for a year, for workmen's compensation purposes, and all compensation claims drawn on this sum by the agent for workmen's compensation alone. This would centralize the finances

of the act and prevent a possible duplication of payments that might arise where each department pays its own claims.

#### STATISTICS.

One hundred and thirty accidents, including two deaths, were reported from March 10, 1914, to Sept. 1, 1916. Thirty-three cases have applied for compensation and have been paid a total of \$3779.23. Out of 97 cases, no time was lost at all in 52, while the remaining 45 returned to work within the two-weeks' limit. There were 2366 days lost. The medical expenses were \$532. Approximately 600 men were included within the provisions of the act during each year.

#### QUESTION OF INSURING IN A PRIVATE INSURANCE COMPANY.

The principle of insurance is,—to pay the losses of any one subscriber from the combined premiums of the whole. If the city insured in a private insurance company, it would pay a definite yearly premium to the company to operate its insurance. A serious accident, with heavy losses, that now must be borne by the city alone, would then be paid by the company out of its combined premiums. To insure in one of the stock companies, the premium, based on a payroll of approximately \$500,000, would cost the city \$10,000 per year.

Few companies will accept city business because the large risks makes it unprofitable. The underwriting is difficult as the exact definition of the terms, "laborers, workmen, and mechanics," has not as yet been determined. If a court decree should include within the provisions of the act a class of employees that were not calculated on in the premium, the company might suffer heavy losses.

A mutual insurance company formed by all the municipalities insured by the act might be created. The chief administrative officers of the municipalities could direct the company. This company might be able to give a more equitable rate than the stock companies that now handle this business. If it were not desired to start an entirely new company, the Massachusetts Employees' Insurance Association, a mutual company of employers originally created by the Massachusetts Legislature to handle all the workmen's compensation business in this state, might be authorized by law to create a special department for the administration on a mutual basis of municipality insurance. Small municipalities, on whom large losses would be a heavy burden, would greatly benefit from association in a mutual insurance company, particularly if it were under state control.

The objections to insuring Cambridge in a private company, especially in a stock company operated for a profit, are many. The city is a \$130,000,000 corporation, with a complete or-

ganization that can be used for insurance purposes without extra expense or the expenditures for administrative purposes demanded by the private companies. No profit is derived from the insurance by the city,—practically the entire payment is given to the man for compensation. The administrative expenses for the city are the salary of the agent and the fees of the physician. If special care is taken to prevent accidents, and only employees in good physical condition are chosen, the city can continue to operate profitably its own insurance. Already some of the large business corporations run their own insurance, especially when they have made a physical examination of all their employees and divided them into liability groups, according to their physical condition.

#### PHYSICAL EXAMINATION OF EMPLOYEES.

A physical examination of all the city employees covered by the act might be feasible, when they are hired, and periodically afterwards. Physical defects would be discovered and the men could be placed at work suitable to their physical condition. The city would be protected from false claims for injuries alleged to have occurred during employment, but which in reality were chronic diseases. A record of serious physical defects, such as hernia, joint trouble, syphilis, varicose veins, or any of the common chronic conditions could be compiled, and would be of service in adjusting claims.

When the large liabilities that the city assumes in operating its own insurance are measured, the necessity for a knowledge of the employees' physical condition is obvious. There are no provisions in the act for the relation of physical defects to injuries. A recent Supreme Court decree states that in the act "there is nothing said about the protection being confined to healthy employees. This act makes no distinction between the wise and foolish, skilled or inexperienced, healthy or diseased employees. It is the injury arising out of the employment and not out of the disease of the employee, for which compensation is to be made."<sup>18</sup>

To allege that an injury arose out of the employment and was not a long-standing condition is not difficult. If it can be shown that a pre-existing organic condition was accelerated or aggravated by an injury, compensation is allowed. In practice, such chronic conditions might have been activated by natural causes; yet, when injury is alleged, it is difficult and expensive to prove that it is not the injury, but the physical condition, which caused the disability. Syphilis, in any of its forms, is a hazardous disease, because of the long period of incapacity that can accompany it.

Men in poor physical condition are often employed by the city, and are protected by the Civil Service regulations, so long as they remain on good behavior. A city is expected to harbor its unfortunates and not be too rigorous in its

demands for a full service return from its labor. With the acceptance of the Workmen's Compensation Act, it is questionable if this policy can be longer followed. Every employee now becomes a potential hazard. Large sums of money can be lost and debts shouldered on the city for years to come by compensation claims. Men who are physically unable to perform the city work, and have a recurrence of organic disease, must be paid the same compensation as those receiving legitimate injuries. Only a physical examination of the men will protect both the men and the city. Later the Legislature may enact special rates and conditions for those suffering from chronic disease and liable to become financial burdens on the insurance. The framers of this act never intended it to become a pension for weaklings or those who were physically unfit prior to employment. For the present, reliance must be placed entirely on accident prevention, to keep the compensation claims within reasonable limits.

#### PREVENTION OF ACCIDENTS.

Pain and suffering will be lessened for the man, and the city will be saved financial losses by the prevention of accidents. Part of the premium of all insurance companies is spent for accident prevention and safety inspectors.

The city has recently started a campaign for the prevention of its accidents. Every foreman is urged to act as a safety inspector in his department. The formation of a safety committee according to this tentative plan is under way. A general committee, to consist of all the foremen, will inspect dangerous places, make recommendations for guards on machinery, and draw up safety regulations; an administrative committee of the superintendents and the city engineer will order the suggestions carried out.

#### CONSIDERATION OF THE TWO DEATHS.

A street department employee was thrown into the machinery of his sweeper and killed, when it was struck by an automobile. The sweeper was operated by chains and gears that might have been enclosed.

A water department employee in 1915 was struck by a train and killed. He was urinating under a railroad bridge instead of using the station toilet. This dangerous practice should have been prohibited by the foreman.

These two deaths cost the city \$4000 each, while the families lost one of their members.

#### WHAT CITY EMPLOYEES ARE INSURED UNDER THE ACT?

There is as yet no classification in the city determining exactly the employees insured by the act. The law merely specifies laborers, workmen, and mechanics, without defining the types of employment to be included within these terms. Neither has the Industrial Accident

Board defined the limits of these terms. Practically, the board has determined that employees who work with their hands and not with their brains are the classes to which the legislature intended to give the benefits of the act. The office forces, school teachers and city officials are considered brain workers; the street, water, park and sewer employees are termed manual laborers. Questionable cases must be referred to the board for judgment, and the board will decide by considering the exact nature of the work at which the man was employed at the time of the accident. Important rulings will probably be referred to the Supreme Court for final decision.

The terms "laborer, workman and mechanic" have partly been defined by a recent decision of the Supreme Court which reads in part, "A 'laborer' ordinarily is a person without particular training who is employed at manual labor under a contract terminable at will, while 'workmen' and 'mechanics' broadly embrace those who are skilled users of tools." The Civil Service classification has partly assisted in defining these terms. Although their classification is for Civil Service purposes only, the commission has tried to include in the Labor Service only such men as work with their hands all the time.

City firemen and, by virtue of the same decision, city policemen, have been excluded from the provisions of the act by a recent Supreme Court decision in the Devney case.<sup>10</sup> Mr. Devney, a Boston fireman, was killed in the engine house where he was stationed by falling down the pole-hole. It was thought that the young man had a nightmare, imagined that an alarm had rung, walked to the pole and fell to the floor below. The Industrial Accident Board decided in favor of the dependents, but the Supreme Court reversed the decision. The court decided that the Civil Service rules "classified a fireman, employed by the city, in the 'official service' and not in the 'labor service,' which is divided into 'laborers,' 'skilled laborers,' 'mechanics and craftsmen.'" A discussion of the case develops that firemen take examinations to be appointed, wear uniforms, and are considered to be public officials charged with the performance of certain public duty or service. They have always been recognized as a distinct class, and if the Legislature had intended them to be included within the provisions of the act, it would have been plainly so stated.

#### PENSIONS AND VACATIONS.

The city allows two weeks vacation with pay each year to every laborer. This vacation has been taken advantage of in connection with the administration of the compensation act by the city. When a man is injured, he is immediately given his vacation on his request. This assures him of his regular weekly income during the first two weeks after the accident, while the law merely gives free medical attention.

Under the state law,<sup>11</sup> city employees are granted a pension after a certain term of service. The older employees who receive small injuries are urged to take advantage of this pension. When injured they may accept either compensation or pension, but not both.<sup>12</sup>

#### SPECIAL POSITIONS FOR INJURED MEN.

The superintendents are requested to hold certain positions open for the men who have not wholly recovered from the effects of their accidents, but have returned to work. Such positions are, driving a team, acting as watchman, or other work of a light nature. This enables the man to earn his full wages and saves the city compensation.

To return men to work at the earliest possible time is the policy of the medical department. Effort is made, not only to institute a medical cure, but to restore function so that the man may resume his former work quickly. A fractured leg may be in good position and strongly united, but if the knee joint is stiff and the muscles atrophied, the man will still be incapacitated from work, although he is medically cured. Measures to restore function should be coupled with medical treatment.

#### SATISFIED WITH THE LAW.

The employees are well satisfied with the operation of the law. They now have definite rights and are no longer subservient to others for an adjustment of their claims. Each year the benefits of the act are increased by the Legislature.

The death cases are being settled on a basis of \$10.00 a week for 400 weeks till a total of \$4000 has been paid to the dependents.

TABLE 11.  
TIME LOST.

DATE	TIME LOST IN DAYS	NUMBER OF CASES IN WHICH NO TIME WAS LOST	PERCENTAGE OF CASES RETURNING WITHIN 2 WEEKS AND RECEIVING NO COMPENSATION
Mar. 10, 1914 to Jan. 1, 1915	382	5	40%
Jan. 1, 1915 to Jan. 1, 1916	1630	26	76%
Jan. 1, 1916 to Sept. 1, 1916	354	21	80%
TOTAL	2366	52	65% aver.

The decrease in time lost in days and the increase in the number of cases that have lost little or no time has resulted from the policy of giving the employee light work until able to resume his former activities. The measures taken to restore a man's functions, as well as to perfect a medical cure, have also aided in reducing the time lost.

TABLE 111.  
MEDICAL EXPENSES.

DATE	MEDICAL EXPENSES
Mar. 10, 1914 to Jan. 1, 1915	\$24.00

TOTAL . . . . .	\$518,574		\$10,342

The medical expenses have been unusually small for the work. Many cases were found to have had no bill; the patient himself probably paid the medical expense.

In this classification of employees, only those who are probably included within the terms "laborers, workmen, and mechanics" were considered.

The pay-roll figures were taken from the list of department expenditures for 1915-1916, printed in the proposed budget for 1916-1917. Where they were incomplete, recourse was had to the annual report for 1915.

The probable premium rate was taken from the stock companies' manual of rates. An expert underwriter checked them up.

up in this proposed legislation which is, in effect, an extension of the principle involved in the former legislation. We can learn something by studying what has been done in other countries. In this communication I shall endeavor to be brief and to touch upon simply salient points. From other countries we may learn that voluntary insurance has, in almost every instance, proved a complete failure; also that the evil results of medical attention paid on the capitation plan have been everywhere evidenced much as they are today in lodge practice. We may also learn one great fact from the history in England where, after the physicians had protested the terms of the proposed act through their organized body, the British Medical Association, and had agreed with practical unanimity not to work under the act,—on the day after the act was passed 10,000 physicians applied for positions, and, within a week, 15,000, causing the British Association to acknowledge that it had been defeated, and to release its members from the pledges previously given.

The statistics of charitable organizations show that about 33 1/3% of the cases of dependency in the Commonwealth are due to sickness, and about 26% to non-employment. If non-employment could be insured against, and if sickness could be lessened by preventive measures, and the time of disability due to sickness diminished by the best possible treatment, then the economic advantage to the Commonwealth would be great. This implies that in any proposed scheme boards of health must be included that prophylaxis must be emphasized, and that the quality of medical service must be of the best; that serious cases must be placed in the hands of experienced physicians; and that in the scheme must be included the attention of

## INDUSTRIAL HEALTH LEGISLATION.

By FRANCIS W. ANTHONY, M.D., HAVERHILL, MASS.,

*Member of the Medical Committee Advisory to the  
Industrial Accident Board  
President, Massachusetts Society of Examining  
Physicians.*

THE question of legislation which is contemplated in regard to industrial health insurance is of great importance to the physicians of the Commonwealth. It is particularly important that before any legislation is enacted, physicians acquaint themselves with what is proposed, and fully realize what an act of this sort may mean to the profession. The complicated questions that arose at the time of the Workingmen's Compensation Act are mere trifles as compared with the many-sided problems that come

specialists and the employment of hospitals whose work conforms to an established standard. It also implies that there must be a certain standardization of physicians. It is true that all men practising medicine in the state of Massachusetts have been licensed by the Board of Registration, but not only is it true that scarcely a man in the State is competent to practise medicine if we include in that term treatment in all its specialties, but also it must necessarily be true that there is every degree of competency in the profession. Few general practitioners are willing to operate upon an injured eye, and the number of men in a given community who are competent to do an intestinal anastomosis is small. In the practice of today it is the custom of the great majority of the physicians of the State, competent as they doubtless are to diagnose and treat the ordinary ailments of their patients, to call to their assistance men whose opportunities have been greater in diagnosis, or those who have laboratory facilities impossible for the ordinary physician, or to call those specially trained and experienced in surgery, neurology or this or that special branch of medical work.

Any plan, therefore, for utilizing services of the profession at large must include in it the recognition of the necessity for securing the services, either directly or as consultants, of the best trained men in the State.

From the practical working out of the Workmen's Compensation Act we can also learn a great deal. First, every profession, as Dr. Cotton has well said, contains a certain percent. of undesirables, and if, in the medical profession we estimate this number even as low as 5%, which is probably not far from the real truth, still no legislation can be framed that does not take into consideration this small percentage, and which is not framed so as to prevent them from becoming a menace to all with whom they are connected. A physician who for several weeks treats as a sprain a fracture of the thigh, one who regards as a malingeringer a patient suffering from a fracture dislocation of the vertebrae, one who presents a bill of \$20 for four office visits of a man suffering from a contusion of the thumb, one who, not surgically expert, enters into a contract to do work requiring good surgical judgment—any one of these men is not proper to render such service as a compensation act requires, whether he attempts to serve the injured party directly in the relation of physician and patient, or whether he expects employment from an insurance company that takes a narrow view of what is best, not only for the patient, but also for itself. Second, those who have been in close touch with the work throughout the State have learned that, quite a per cent. of those earning low wages in employment in Massachusetts, are not only *not* insistent upon the free choice of their physician, but really express little interest in the matter, provided that their bills are met. While it is

claimed that every workingman has the inalienable right to choose his own physician when sick or injured, it is as true that he has the inalienable right to elect whether he will employ a physician of his choice, or will accept service that is rendered him at no expense to himself. Third, we have also learned that there is quite a percentage of physicians who do not care to enter upon industrial work. Fourth, that there are plenty of physicians who will take the work in any form that it is offered. Fifth, that insurance companies of good standing prefer good work for financial reasons if no other. In other words, that there is the same difference between insurance companies that there is between individual physicians. Again to quote one of Dr. Cotton's terse statements, "Were all injured people honest, were all physicians honest, were all insurance companies honest, the problem would be simplicity itself." Sixth, with properly equipped plant hospitals much can be done at relatively low cost. Seventh, that any plant hospital or other hospital that does not bring the patient in *personal* touch with a physician of standing and qualifications is not valuable. Eighth, that some insurance companies will abide by a gentleman's agreement, while others seemingly will not. Ninth, that the best obtainable service is in the end the cheapest. Tenth, that there must be a following-up system during convalescence. Eleventh, that prevention avoids trouble.

If the proposed health legislation goes through in the form of a bill, the physicians of the State must not be caught, as they were at the time of the action relative to the compensation act, namely, in a state of soporific somnolency. The progress of the legislation must be carefully watched, and the members of the legislature must be impressed by the physicians who know them, with the fact that there are in this bill large medical questions involved. If such a bill passes it should not be so framed that the capitation plan of insurance is used. Personally, I believe it would be very disadvantageous, both to the workingman and to the physicians if the insurance was developed so that it was a State insurance. This would mean political appointments, and that means inferior service. The bill should be so framed that the medical services be paid for per visitation, but there must be with this a limitation to the charge. The most satisfactory measure yet devised, I believe to be that recommended by the medical committee advisory to the Accident Board as a basis for the compensation under that act, namely, the average minimum rate for the same kind of service rendered in the locality in which the accident (or sickness) occurs. When we remember that most of the medical services rendered families of those who earn under \$750 a year is *now* gratuitous, the minimum rate ought certainly to procure medical attention of the proper grade.

The bill should be framed so that, *at the start, every physician licensed to practise in the State, who desires to take up this line of work, should have the opportunity to register his name; but, to remove the incompetent and undesirable, a strong central board with deceptating power should be incorporated in the act. This board should have medical representation upon it.*

The number of patients or families to be treated by one physician should be limited: first, in order to avoid the consequences necessary to too much work, namely, poor service to the individual; and, second, as far as possible, to divide the work. It will always be true, as is now true in private practice, that some men will be more popular than others, either owing to real greater efficiency, or to their possession of those faculties or qualities that appeal to the popular taste. As in private practice, so in work of this nature, these assets of a given physician will be valuable to him as a direct benefit, and nothing can prevent their being such a benefit; the only direction to be undertaken is that they do not impose upon him an amount of work that he cannot properly handle.

There must be provision for specialists, for the masseuse, for the dentist and for apparatus. There must be medical referees, not local, to settle disputes. The charge for medical referees, hearings, etc., must not be debited to the medical expense, because it does not belong there, but is really a part of the administration of the act. The reports of medical referees must stand as evidence at hearings, otherwise the type of man required for a referee could often not be obtained, owing to the inability of a man of this grade to give up the time necessary to attend long-drawn-out hearings. Group work should be encouraged, provided that this group work conforms in its units and in its whole to a *definite standard*. It should not be possible to allow a group of men to join forces in work under this act unless some competent authority passed upon the question whether those taking up a special line of work had special training and ability along the line assumed. But, granting that a definite standard was established, the highest benefit must ensue to the workman if his case was passed upon by a group, each one of which had a special training. Arrangements must be made to cover the questions of changing doctors, this being permitted at the request of either the physician or the patient upon the approval of a referee.

I have written enough perhaps to call the attention of the profession to the broadness of the scope of the question involved in this act and of its vital importance to the profession as a whole. Some of the most important features are these: If this legislation is adopted, and goes through in the form of *State insurance*, it is the opinion of those who have carefully considered the matter that it means the ruination

of the practice of from 20 to 30% of the physicians now engaged in the Commonwealth, if there is included in it a plan by which those earning more than a minimum wage can share its benefits. If it goes through and is placed in the hands of insurance companies who are allowed to select an individual or an extremely limited panel, the effect upon the profession of the State will be practically the same. If it goes through and a panel is formed, wide open at first, but reduced rapidly and purged of the incompetent and undesirable, the best interests of the workmen, of the physician, and of the companies will be assured.

A committee of the Massachusetts Medical Society, consisting of Dr. Frederic J. Cotton of Boston, Dr. W. H. Merrill of Lawrence and myself, have been in touch with the recess committee of the Legislature, who are this summer and fall considering the question. They have received us always courteously, and listened with attention to what we have presented. I know that the other members of the committee feel, as I do, that our task is Herculean, and that we need the assistance, advice and friendly criticism of the profession at large. Our most difficult task has been to get the profession to realize that there is under consideration a measure which means so much to them, and that they should feel that the inception of a measure of this sort is the time to see that the rights of the profession are safeguarded. I believe that such legislation is coming within a few years, if not coming this year; that it will be advantageous to the poor, who at present earn a wage insufficient to allow them to pay for medical care, *provided* that the act is so framed that the workman receives the attention, not of the poorest members of the profession, not of inexperienced men learning the profession in large hospitals, but of the men best equipped for medical service. The man who, recognizing the future, is not now equipped to render satisfactory service, or who does not, in view of the future, well and thoroughly equip himself for such service, will, in the future, bitterly complain, but will not deserve sympathy. I sincerely hope that every physician will examine and carefully consider these questions, not from a narrow standpoint, but from the broad utilitarian standpoint, of what is best for the Commonwealth as a whole.

RECALL OF HEROIN.—Report from Washington on December 12 states that Dr. Rupert Blue, Surgeon General of the United States Public Health Service, in a circular order to all commissioned medical officers of the service, has ordered the dispensation of heroin and its sale at relief stations to be discontinued and all stock of the drug returned to headquarters.

## THE MEDICAL DEPARTMENT OF A MODERN INDUSTRIAL PLANT.

By F. O. WEST, M.D., WOBURN, MASS.

THE development of the medical department of a modern industry engaged in a dangerous trade (the manufacture of phenol, benzol and picric acid) shows recognition of its responsibility in providing adequate medical service to its men, and emphasizes its desire to comply with the spirit of the law, as well as the letter.

At the beginning, the department was conducted in a small pump house (Fig. 1). Treat-

FIG. 1. ORIGINAL FIRST-AID ROOM.

ment was given by a member of the guard who was stationed at this part of the plant, and who had had some experience in first-aid work. He was still a member of the guard and did the other work simply as a side issue. The serious accidents were cared for by the first outside physician available, and in case of the need of hospital care, the injured man was transported over a rough road for three miles in a horse-drawn ambulance. The supplies of the department were merely those prescribed by law. No records were kept except in the serious accidents causing disability, and the system in this regard was uncertain and very unsatisfactory.

This situation soon became entirely inadequate, both as to housing and service. To improve conditions, the department was moved into a larger building, but in which the pump, to be used in case of fire, was also housed. The attendant was still a member of the guard, but was detailed to do nothing but this work, and he was assisted by another man, who took care of the night shift. More supplies were added, but the clerical work was still done by a member of the office clerical staff when he had any leisure time.

Finally, under the direction of Dr. W. F. Boos, of Boston, the consulting physician of the plant, the next and final development took place, and on March 1, a fully equipped hospital was built and put in operation. (See Fig. 2.) This is a sheet-iron building erected as a hospital and used solely for medical purposes.

It consists of: a four-bed ward, in which is also kept, because of lack of room elsewhere, the operating table and instrument cabinet; a room for the first-aid, possessing all the supplies and

FIG. 2. PRESENT HOSPITAL BUILDING.

equipment of the out-patient surgical room of our largest hospitals; with the addition of two lung motors; a pharmacy for the medical and surgical supplies, with facilities for making and compounding any preparations that might be needed; together with an ice box and an electric range; a bathroom containing a full-length tub, and a shower bath; in this room there is also a high-pressure steam sterilizer; the resident surgeon has an office with scales, clerk's desk and filing cabinets; and a small laboratory which is equipped with all reagents for ordinary work, a microscope and a water-power centrifuge. The seventh room is set aside as a living room for one of the first-aid men. On the west end of the building is a piazza and a fumigator for fumigating mattresses. A large electric fan gives ventilation. There are linoleum floors in three rooms, the others have hard wood.

The personnel of the medical staff was also enlarged. On February 1, the writer was appointed resident surgeon, and devotes part of the day to the plant, and is on call for accidents. The first-aid force became separated from the guard and was increased to three men, one of whom was a pharmacist. With one man sleeping in the hospital during the night, we have a service with two men available at all times. To handle properly the vastly increased clerical work, our department has a clerk who devotes his entire time to the work made necessary by the many reports required, and by our complete system of case records.

In addition to this well-equipped hospital that is able to handle, for a time at least, the most serious accidents, and keep for any length of time accidents that do not require expert nursing, we have established emergency stations in all the buildings, which have reagents suited to their peculiar needs. These racks are inspected daily by a member of the hospital department, and all reagents kept supplied. On the daily rounds of the plant this man comes in constant touch with the workers, and is able by constant

reiteration to educate them in their personal care.

The first-aid racks are intended simply to relieve at the time of accident; further treatment is carried on at the hospital. Employees are instructed to report immediately after the accident, and not to let even the slightest scratch go untreated. To our vigorous campaign, we feel confident the absence of infected wounds can be attributed. Of the 1648 accidents treated from March 1 to October 1, we have not had a single infected wound when the man reported at the time of accident, and only two infected wounds due to failure to report till infection set in. One of these was a septic hand, occasioned by an employee attempting to remove a splinter from his palm with a dirty tobacco knife; three days later he reported for the first time with a palmar abscess. The other case was a septic finger; infection entered through a small abrasion, which was neglected; this man also failed to report till his finger became swollen and painful.

In cases where it seems inadvisable for the injured to return to his home, either because he needs observation as a result of "fume" poisoning, or because rest is needed, the patient is put to bed in our ward and is kept as long as required. As before mentioned, in cases of grave nature demanding expert nursing, the patient is transferred to a hospital. If a man demands to be sent home and requires farther treatment, he is cared for there. An x-ray apparatus, the property of the resident surgeon, is available when needed, and all fractures and doubtful cases are so examined.

All accidents are carefully tabulated, giving the total number, character of injuring agent, location of injury, and department where the injured man is employed. Not only do we have accidents peculiar to our line of industry, but we have many common accidents that will occur about a large plant, from scratches to wounds requiring many stitches, and from contusions to fractures. Moreover, we have not confined our services to accidents alone, but have also included any medical ailment that the man may present. We have a list of 41 different complaints of a medical nature, that the men have called on us for; this list including such as hemorrhoids, headache, constipation, frontal sinusitis, warts and scarlet fever. No man is sent away without something being done, and we feel that much working time has thus been saved, not only to the company, but also to the men themselves.

Probably one of the most important functions of the hospital department is the examination of the new employees. In the case of the pleuric plant this requirement is rigid, and every man must receive the consent of the physician in charge before he is allowed to go there to work. As a result, 9% of the men who have applied for this work have been rejected, causes for rejection being arteriosclerosis, mediastinal tumor,

heart lesions, asthma, albumin and casts, and chronic bronchitis. Without question this system has been the means of averting many accidents arising from "fume" poisoning.

The accident prevention feature of the hospital department is also of great value; not only are the men cautioned and instructed on the first-aid man's daily trip around the plant, but they are continually being advised as to safety when they call at the hospital. They are instructed, among other things, in regard to the proper clothing to wear, and are repeatedly told that goggles are available at all times. In addition to this, signs are posted through the buildings warning the men of the dangers. The equipment on hand for protecting employees, consist of goggles, respirators, helmets, pump for supplying air to men working in tanks, rubber gloves, boots and suits.

The department is thoroughly organized and gives a monthly average of 965 treatments of all classes. The men have gradually come to look upon the hospital as a place for their benefit, and have ceased, in a large measure, to regard it with suspicion. The spirit of the officials is admirable, and they have sought to cooperate in every way possible, and have never refused to provide anything asked for.

### Book Reviews.

*The Operating Room.* By AMY ARMOUR SMITH, R.N., Superintendent of Nurses at the Woman's Hospital of the State of New York. Philadelphia and London: W. B. Saunders Co., 1916.

This volume, intended as a surgical primer for pupil nurses, is a synthesis of operating-room technique. It is divided into a series of twenty-two convenient chapters dealing with various aspects of this important subject. Particular commendation is due to the chapters on terms used in surgery and the lists of instruments needed for various operations. Not all surgeons would, of course, agree in the details suggested throughout the work, but in the main it merits cordial approval. The book is well illustrated with fifty-seven selected text figures.

*The Practitioner's Vestibular Test.* Philadelphia and New York: Lea & Febiger, 1917.

The issue of this well-known style of test for 1917 contains the usual memorandum pages and in addition thirty-two pages of useful and convenient tables and data. It is published in four styles, weekly, monthly, perpetual and for sixty patients. It should continue its service and utility to general practitioners.

EDWARD C. STREETER, M.D., *Chairman*  
WALTER P. BOWERS, M.D., *Clinton*  
ALGERNON COOLIDGE, M.D., *Boston*  
HOMER GAGE, M.D., *Worcester*  
JOEL E. GOLDTHWAIT, M.D., *Boston*  
LYMAN A. JONES, M.D., *Boston*  
ROBERT B. OSGOOD, M.D., *Boston*  
HUGH WILLIAMS, M.D., *Boston*  
ALFRED WESTCOTE, M.D., *Waltham*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, \$6.50 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager*,

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

## MEDICAL ASPECTS OF SOCIAL INSURANCE.

The current number of the JOURNAL, devoted to the medical aspects of social insurance, reflects only in a small measure the great importance of the subject. Social insurance in its many phases is still but little understood in this country. It is to be feared that it is only too true, as pointed out by various contributors to this number, that the medical profession has lagged behind in its interest in and its understanding of this new development which will inevitably cause a considerable upheaval in medical practice. As Dr. Cotton points out, the medical profession was caught unawares in the Massachusetts Workingmen's Compensation Act. This has led to an unfortunate feeling of resentment against all forms of social insurance. Perhaps the general attitude of the medical profession in regard to social insurance in general might be summed up somewhat as follows:—

Workingmen's compensation has come, and

we physicians do not think we have been fairly treated. Sickness insurance seems bound to come, and we suppose we have got to make the best of it, but we are going to fight it, and we hope that we can make an arrangement which will be satisfactory to us.

This rather fatalistic viewpoint is peculiarly unfortunate.

Social insurance ought to stand on its own merits, and its acceptance ought to be decided by the predominance of the benefits over the hardships. At the same time social insurance should not benefit any one group to the marked detriment of another group. In other words, while the medical profession is morally obligated in all reason and propriety to protect its own interests, it must view social legislation as a whole, and not that particular part of it which affects itself. This attitude is peculiarly important at the present time, since the last legislature saw the introduction of a bill for a statewide sickness insurance scheme. A state commission is now studying sickness insurance in addition to other forms of social insurance. This commission will report to the incoming legislature. State commissions are at work in California and other states. Presumably bills will be introduced into the legislatures of this and other states for sickness insurance, and it is likely that, in some states at least, some form of sickness insurance will be enacted into law. It would be indeed unfortunate if the medical profession of this state or of this country were to be put in the position of our British brother practitioners who found themselves, on account of a determined and somewhat unreasonable opposition to a movement to which they had valid objections only to a part, in the end completely ignored and apparently humiliated with the resultant loss of prestige to the profession as a whole.

Space does not permit the discussion of sickness insurance, or health insurance, as it is now known, in all of its broad aspects. There are a few considerations which may be briefly discussed.

The paramount consideration must be the need of such insurance. On this point ample data are now available. In the first place, statistics show the close relation between sickness and poverty. The absence of even a single pay envelope to the workingman often spells disaster. An important part of the program of sickness insurance is to continue a reasonable propor-

tion of the pay envelope during illness. It is evident that this helps to feed and clothe the family of the worker as well as the sick worker.

In the second place abundant statistics show that a considerable proportion of the poor who are out of work on account of illness receive no medical attention. From every point of view, particularly that in regard to early diagnosis and preventive medicine, such a state of affairs is undesirable. The aim of all sickness insurance schemes is to furnish medical service to all of the insured. From the point of view of the practitioner it will mean that there will be a larger number of sick to be attended, but it will also mean a sure recompense for this attendance. There is no general practitioner who, moved by the poverty of the workingman who is ill and without his pay envelope, does not in innumerable cases furnish his services either gratuitously or practically so. Under any scheme of health insurance the practitioner will be paid for such services. It is true that it is customary to compare the presumable services of doctors under any health insurance act to the rightly despised lodge or contract practice. It would be obviously intolerable that all practice under the workings of a health insurance act should descend to the low level of much of the lodge and contract practice. However, it should be remembered that lodge and contract practice are but the sporadic, ineffectual and ill-advised attempts on the part of poorly organized groups in the community to secure the benefits of sickness insurance. We can see in these groping efforts the underlying demand for sickness insurance. This demand has taken form in lodge benefits, fraternal orders, employers' establishment funds and the funds of certain unions. But the working of all these methods is haphazard, uneven, many times unjust and unfortunately does not include, because it is not uniform and compulsory, those who are in most need of sickness insurance. There is no good reason to suppose that the workings of any state sickness insurance scheme will not at least approximate the workings of the best of the well organized establishment and union funds under which many physicians already work with great satisfaction.

There is no doubt that the adoption of some scheme of sickness insurance will compel a rearrangement of medical practice, but it is our belief that, despite inconveniences, the medical profession will be benefited rather than injured by a proper sickness insurance act in

Massachusetts. Sickness insurance seems to us to be a long step toward the betterment of social conditions. Nevertheless there is ample opportunity for the introduction of unjust administrative details. We have the experience of Germany, of England, and of the Compensation Act in Massachusetts as guides to avoid possible pitfalls. It seems to us that the nature of the problem is rather different from the Compensation Act. In that Act the employer is essentially the sole contributor, and the insurance company the main administrator. Under sickness insurance, if the control is democratically divided between the three contributors, namely, the employer, the employee and the state, and if the administration is placed in the hands of local carriers, which are necessarily democratic, and readily susceptible to the local influence of the people who pay the bills, many of the difficulties and objections now arising out of the Compensation Act can be avoided. The administration of sickness insurance by the great insurance companies, mutual, perhaps in name, but not in administration, is certainly most undesirable. We bespeak, therefore, for health insurance a kindly and sympathetic as well as a critical attitude on the part of the medical profession.

#### SMALLPOX IN ROXBURY, MASSACHUSETTS.

THE recent outbreak of smallpox in the western part of Massachusetts, and the occurrence on December 7 of a case of the disease in Roxbury, appropriately calls renewed attention not only to the activity and vigilance of health departments but also to the importance of repeated universal vaccination for the complete protection of the community. Arrangements have been made in Boston for free vaccination at 17 Blossom Street, the headquarters of the West End Health Unit. Arrangements for vaccination in homes may also be made by telephoning to the Boston Health Department at Fort Hill 5100. Dr. F. X. Mahoney, health commissioner of Boston, has issued the following statement relative to the disease and the menace which it constitutes in the community:

The recent outbreak of smallpox in the western part of the State should serve as a warning to all unvaccinated persons in this city. Protection of ourselves from smallpox in this city can be obtained only by the vaccination and revaccination of its citizens.

"A study of this disease in Boston for the past 30 years shows conclusively that epidemics have occurred at intervals of 10 to 15 years. As a result of the outbreak of 1893-4, the city was well vaccinated and the disease necessarily disappeared. From that time until 1901, the next outbreak, the city was free from this disease with the exception of occasional cases that are imported into every large city.

"In 1901, after a lapse of eight years, the majority of the people had lost their protection by vaccination, and the disease again appeared in epidemic form, and before being brought under control 1500 cases and 277 deaths occurred. This great number of deaths from a preventable disease is a heavy toll for any community to pay when vaccination, which will afford absolute protection from this disease, is free to everyone in the city.

"At the present time in this city there are thousands of people who, vaccinated in infancy, have probably lost their protection from this disease; and also many thousands more who have arrived in this city and who are as yet unvaccinated.

"It is the duty of parents to see that not only themselves but their children are safeguarded and protected from this disease by vaccination."

In this connection there is interest in an opinion recently given by Attorney-General Attwill in reply to the following questions relating to vaccination and the validity of certificates for exemption from vaccination:

"Must the physician make a personal examination?"

"Must the physician making a personal certificate be the one who makes this examination?"

"Must the certificate be so worded that it shows that it is the opinion of the examining and signing physician that the cause stated is sufficient?"

"Must not the certificate be so worded that it gives it as the opinion of the physician who signs the certificate that the child is not a fit subject for vaccination?"

For the guidance of physicians, Mr. Attwill's reply may be quoted in part as follows:

"In answer to the questions submitted by you, assuming they relate to school attendance, it is evident that if a child desiring admission to a public school presents a certificate, signed by a regular practicing physician, that 'he is not a fit subject for vaccination,' with the 'cause stated therein,' the statute is complied with. Under this chapter a personal examination by a physician is not necessary, and hence your second question does not require an answer.

"Your third question is to be answered in the negative, and your fourth question in the affirmative. The statute expressly provides that the exemption certificate shall state that

the child 'is not a fit subject for vaccination.' That necessarily is a matter of opinion, and, as such, is the opinion of the physician signing the certificate. It would not seem necessary to require such physician further to emphasize his opinion by asserting that it is also his opinion that the cause stated is sufficient to justify his statement.

"The cause stated, in my judgment, must be an adequate and lawful one in order to give the certificate validity. A cause absurd on its face, showing a deliberate intent to evade the statute, would not be, in my opinion, a compliance with it."

## INDUSTRIAL HEALTH INSURANCE.

As we have pointed out in a previous editorial, the present issue of the JOURNAL is published as a special number devoted to the subject of industrial health insurance. The JOURNAL has, from time to time, previously discussed various aspects of this question, and will continue to do so until an equitable settlement of the entire problem is reached.

In addition to the material presented in the first part of this issue, attention is called to the publication in the miscellany department of a valuable table sent out by the American Association for Labor Legislation, which presents a compact summary of what other countries have done in the matter of health insurance legislation compared with the proposed provisions of the standard bill advanced by the association. A careful study of this table is earnestly commended to members of the profession. It will be found useful, also, to preserve for reference.

Attention is further called to a letter published in the correspondence column, pointing out what the author conceives to be two fundamental errors in the Doten Bill. As we stated editorially, in last week's issue of the JOURNAL, the original form of the Doten Bill is far from being satisfactory in its medical aspects. This bill is, at present, undergoing revision at the hands of the Massachusetts Commission on Social Insurance, which will, presumably, present a new draft of it before the next session of the Massachusetts General Court.

It is by no means the desire of the JOURNAL to discourage criticism or stifle opposition to the subject of industrial health insurance. For this reason we desire also to call attention to the address made by Dr. Eden D. Delphey, first vice-president of the Federation of Medical

Economic Leagues and chairman of its health insurance committee, at the meeting of the American Medical Association in Detroit, June 12 to 16, 1916, published in the July issue of the *Medical Economist* (pages 155 to 157). Reading between the lines of this article, however, it is obviously not the principle of industrial health insurance, but the proposed methods of its administration to which the author objects, and that is precisely our present subject for amicable discussion. As Dr. Delphy emphasizes, there is not on the face of the earth a more altruistic profession than that of the physician. Opposition to details of health legislation, whatever its source, is fundamentally dependent on real or fancied infringement of personal rights. It is for the physicians in discussing and determining their relation to prospective legislation to carry the same altruistic principles into their action that they do in ministering at the sick bed or in the perilous pursuit of the causes of infectious disease.

#### PROGRESS OF POLIOMYELITIS.

DURING the past week there has been a continued decline of poliomyelitis throughout the United States. The weekly report of the United States Public Health Service for Dec. 8, 1916, notes the occurrence of cases in October as follows: New York, exclusive of New York City, 334; New Jersey, 254; Pennsylvania, 250; Minnesota, 165; Illinois, 151; Michigan, 97; Connecticut, 91; and Wisconsin, 84.

In Massachusetts there were in October 702 cases and 150 deaths. Boston had 63 deaths, Holyoke 11, Lynn 9, Quincy 8, Dalton, Malden and Pittsfield 4, Melrose, Monson, Waketield and Waltham 3, and the following two each: Beverly, Brookline, Cambridge, Gloucester, Lowell, Newburyport, Somerville, South Hadley and Springfield.

Other deaths occurred in Belchertown, Belmont, Conway, Dedham, Everett, Haverhill, Hopkinton, Medford, Newton, Northampton, Stoneham, Swansea, Warwick, Watertown, West Springfield, Weymouth and Winthrop.

The October issue of the Public Health Bulletin of the Massachusetts State Department of Health comments as follows on the incidence and mortality of the disease during that month.

"In spite of the excessive number of cases of infantile paralysis reported during the current month, the total number of cases of communi-

cable diseases reported to the department is considerably lower than the total for the corresponding month last year, and only slightly higher than the total for the previous month of this year. All of the diseases, with the exception of anterior poliomyelitis, smallpox and mumps, show a marked decrease over last year's figures for October, especially diphtheria, typhoid and whooping cough.

"Basing an estimate on the incomplete records received, the fatality rate for anterior poliomyelitis for October bids fair to be a little lower than that for September. The fatality rate for September was 24.7. It will be noted that there is an increase of eighty cases of infantile paralysis in October over the number credited to September, making a total of 702 for the month. This increase has been largely in the metropolitan area. Boston heads the list, with an increase of about fifty-seven; Quincy with one of thirty-three, and Cambridge with one of twenty-two. The disease still persists in the western part of the State, but a diminution in intensity in that section is perceptible.

"Following is a list of towns in which infantile paralysis has appeared for the first time during the month of October:

"Andover, Amherst, Athol, Attleboro, Belchertown, Cheshire, Deerfield, Dennis, Easton, Egremont, Grafton, Halifax, Hatfield, Hollbrook, Hopkinton, Longmeadow, Ipswich, Manchester, Mashpee, Natick, Northboro, Northbridge, Swansea, Templeton, Walpole, Wenham, Westwood, Warwick, Whately, Wilbraham and Wilmington."

#### STATE CONTROL OF MEDICAL PRACTICE.

THE present situation as regards the relation of the medical profession to the public raises the question whether, in this community, we are to learn the bitter lesson taught the members of the British Medical Association who, because of their inertia and lack of initiative, had forced on them, by Lloyd George and an act of Parliament, a reduced fee scale and a legal limitation of freedom to practise medicine as they saw fit. The signs are many of State control widening its scope as our country gets older, in various activities of life, and especially is to be noted a tendency to regulate the practice of medicine through a more intimate supervision over the health of its inhabitants.

Compulsory industrial health insurance is coming. Bills have been introduced into the Legislatures of New York and Massachusetts and in this State a recess committee is studying the question and our State Medical Society, in June,

appointed a committee to attend the hearings of this recess committee so that when the difficult problem is solved, of defining just what obligations the profession shall assume, under the terms of the bill, the doctor's interests may not be disregarded.

Meanwhile the profession, with the assistance of business men, is making attempts to provide expert medical diagnosis and advice to the public at reasonable rates; to be regarded possibly as an offset to the former exorbitant charges of some of the so-called specialists, or the abuse of medical charity, so prevalent in the past. Group medicine, for a long time popular in the West, notably in Chicago, and in certain cities of the East, has recently received a new start in Massachusetts in the activities of the Pay Consultation Clinic at the Massachusetts General Hospital, as noted in the *JOURNAL* of July 6, the "Coöperative Medical Group" recently advertised in circulars, and the "Mutual Medical Association," incorporated at the State House a year ago.

Indications multiply that there is a necessity for the profession to adapt itself to the present medical needs of the public—for does not the profession exist for the care of the sick?—to see to it that the unfit are prevented from practising; that those physicians who are equipped with a meagre education shall not pose as specialists after having taken courses of instruction for a few weeks; and finally to give the present problems most careful thought so that whenever bills affecting the practice of medicine are brought before the Legislature, the profession may present a united front, and men trained in medicine, with well considered plans, rather than untrained lay legislators, may guide the way to wise laws.

### MEDICAL NOTES.

**HEALTH INSURANCE.**—The American Association for Labor Legislation has announced that it will hold its tenth annual convention in Columbus and Cincinnati, Ohio, Dec. 27-30. A preliminary program was recently issued by the Secretary, Dr. John B. Andrews, which provides for seven sessions to be held on health insurance and the eight-hour day, subjects which will be most prominent in state and national legislation next year. Health insurance is now the subject of investigation by state commissions in Massachusetts and California, and bills drafted by the Association, with strong back-

ing, are to be introduced into the legislatures of the principal industrial states next year.

Addresses on these vital subjects will be given during the convention by leading scientific authorities and representatives of labor. "The Need for Health Insurance" is the subject of a paper to be given by the President, Prof. Irving Fisher of Yale; Miss Julia Lathrop, chief of the Federal Children's Bureau, will discuss the Public Protection of Maternity; Miles M. Dawson, insurance actuary of New York city, will discuss "The Principles of Health Insurance," while Dr. Alexander Lambert, chairman of the Social Insurance Committee of the American Medical Association, will discuss Medical Organization under Health Insurance, and the Hon. John J. Lentz, President American Insurance Union, will discuss the Fraternal Societies under Health Insurance.

**AMERICAN MEDICAL EDITORS' ASSOCIATION.**—At the annual meeting of the American Medical Editors' Association held in New York City on October 25 and 26 especial interest attached to the symposia presented on "The Doctor and the Law" and on anti-narcotic legislation. Dr. George M. Piersol of Philadelphia was elected president and Dr. J. MacDonald, Jr., of New York, secretary and treasurer for the ensuing year. The executive committee consists of Dr. C. F. Taylor of Philadelphia, Dr. A. S. Burdick of Chicago and Dr. D. S. Fairchild of Clinton, Iowa. Dr. H. Edwin Lewis of New York was appointed chairman of the publication committee and editor of the journal of the American Medical Editors' Association. It was voted to hold the next annual meeting of the society at the McAlpin Hotel, New York, on June 4 and 5, 1917.

### EUROPEAN WAR NOTES.

**WAR RELIEF FUNDS.**—On Dec. 14 the totals of the principal New England relief funds for the European War reached the following amounts:

Belgian Fund .....	\$192,934.00
French Wounded Fund .....	164,944.76
French Orphanage Fund .....	71,774.80
Permanent Blind Fund .....	50,002.48
LaFayette Fund .....	21,195.03
Wittenberg Prisoners' Fund ..	2,080.65

### BOSTON AND NEW ENGLAND.

**SUFFOLK DISTRICT MEDICAL SOCIETY.**—It is announced that at the meeting of the Surgical Section of the Suffolk District Medical Society at the Boston Medical Library on February 14, 1917, Dr. Willy Meyer, professor of surgery in New York Postgraduate School and Hospital, will present the subject of the surgical treatment of bronchiectasis and advanced pulmonary tuberculosis. The development of thoracic surgery within the past few years gives particular pertinence to this subject; and the distinction of the speaker should ensure a large attendance at the meeting.

## TENDENCIES IN HEALTH INSURANCE LEGISLATION

This table presents only the main features of leading health insurance laws, omitting numerous minor qualifications. Most of the European countries mentioned have, in addition to workmen's compensation for accidents, and health insurance, provisions for the contingencies of invalidity, old age, and unemployment.

	Germany (Adopted 1883; in effect 1884; reclassified 1911)	Great Britain (Adopted 1911; in effect 1912)	Austria (Adopted 1888; in effect 1888)	Netherlands (Adopted 1913; in effect ?)	Norway (Adopted 1909; in effect 1911)	Standard Bill American Association for Labor Legis- lation
<b>Scope of Com- pulsory Insur- ance</b>	1. All manual employ- ees. 2. Other specified em- ployees (foremen, of- ficials, clerks, teach- ers, actors, musi- cians) receiving less than \$600 yearly.	1. All manual employ- ees between 16 and 70. 2. All other employees between 16 and 70 receiving less than \$768 yearly.	1. All wage-earners (ag- riculture, forestry, and homework ex- cepted). 2. All administrative officials receiving less than \$480 yearly.	All employees re- ceiving less than \$300-\$600 yearly ac- cording to locality (domestic servants, certain casual em- ployees, and certain taxpayers excepted). All sickness.	All employees over 14 receiving less than \$124-\$178 yearly ac- cording to locality (certain casual em- ployees excepted).	1. All manual employ- ees. 2. All other employees receiving less than \$1,200 yearly.
<b>Disabilities Cov- ered</b>	1. All sickness. 2. First 13 weeks of in- dustrial accident dis- ability.	All sickness and ac- cidents not covered by workmen's compensa- tion or common law.	1. All sickness. 2. First 4 weeks of in- dustrial accident dis- ability.	All sickness.	1. All sickness. 2. First 4 weeks of in- dustrial accident dis- ability.	All sickness, acci- dents, and death, not covered by work- men's compensation.
<b>Waiting Period</b>	1. For cash benefit: up to 3 days. 2. For medical benefit: none.	1. For cash benefit: up to 3 days. 2. For medical benefit: none.	1. For cash benefit: none, if illness lasts more than 3 days. 2. For medical benefit: none.	1. For cash benefit: up to 4 days. 2. Medical benefit not compulsory.	1. For cash benefit: 3 days. 2. For medical benefit: none.	1. For cash benefit: 3 days. 2. For medical benefit: none.
<b>Maximum Time Recoverable</b>	1. Cash benefit: 26-52 weeks for the same illness. 2. Medical benefit: (1) Until expiration of cash benefit. (2) Additional 52 weeks of convales- cent care optional. 50-75% of wages.	1. Cash benefit: 26 weeks in any 1 year. 2. Medical benefit: throughout life.	For the same illness, 20- 52 weeks.	26-52 weeks in any 1 year, but not more than 13 weeks in a year for an illness for which benefit has been drawn more than 26 weeks in the previous year.	1. Cash benefit: for the same illness, 26 weeks in any 1 year but not more than 39 weeks in any 2 consecutive years. 2. Medical benefit: un- til expiration of cash benefit. 60% of wages.	1. Cash benefit: 26 weeks in any con- secutive 12 months. 2. Medical benefit: un- til expiration of cash benefit.
<b>Cash Benefit</b>	1. Medical and nursing assistance and treat- ment. 2. Medicines and ther- apeutic appliances. 3. Hospital care. 4. Medical treatment to dependents optional.	1. Medical treatment. 2. Medicines and ther- apeutic appliances. 3. Sanatorium benefit for all forms of tu- berculosis. 4. Medical treatment to dependents optional. 5. Dental care optional.	1. Medical treatment. 2. Medicines and ther- apeutic appliances. 3. Hospital care. 4. Medical treatment to dependents optional.	Medical treatment and medicines pro- vided by voluntary sick clubs. Must be open to any insured person. Cash benefit not paid until ar- rangements for medi- cal treatment and medicines are made.	1. Medical and surgical treatment. 2. Therapeutic appli- ances, medicines op- tional. 3. Hospital and asylum care. 4. Medical and surgical treatment to depen- dents, medicines op- tional. 5. Dental care optional.	1. Medical, surgical and nursing assistance and treatment. 2. Medicines and ther- apeutic appliances, costing not more than \$50 in any 1 year. 3. Hospital care. 4. Medical and surgical treatment and medi- cines to dependents.
<b>Maternity Bene- fit</b>	1. Insured women: (1) Cash benefit 2 weeks before and 6 weeks after delivery; or (2) Home nursing assistance or hospi- tal care with half cash benefit. (3) Obstetrical, pregnancy and nurs- ing benefit optional. 2. Wives of insured men: optional.	1. Insured women: (1) \$7.20. (2) \$14.40 if wives of insured men. 2. Wives of insured men: \$7.20.	Insured women: (1) Obstetrical care. (2) Cash benefit for at least 4 weeks after delivery.	Insured women: (1) Cash benefit up to full wages during incapacity due to delivery. (2) Usual cash ben- efit during incapacity due to pregnancy.	Insured women: (1) Cash benefit for 6 weeks. (2) Medical treat- ment.	1. Insured women: (1) Cash benefit 2 weeks before and 6 weeks after delivery. (2) Medical, surgical, and obstetrical treat- ment and appliances. 2. Wives of insured men: medical, surgical, and obstetrical treatment and appliances.
<b>Arrangements for Medical Service</b>	1. Free choice between at least 2 physicians under written con- tracts with funds, if cost is not exces- sively increased. 2. Insured may be paid cost of medical ser- vice if reasonable con- tracts with sufficient physicians cannot be made.	1. Free choice among panel of physicians whose pay is ar- ranged by Insurance Committees accord- ing to official regu- lations. 2. Other arrangements permitted if num- bers on panel are in- sufficient.	Free choice among phy- sicians under con- tract with funds who may be paid: (1) Fixed salaries; (2) Capitation; or (3) By the visit.	Free choice between at least 2 physicians under contract with sick clubs.	Contracts with phy- sicians by funds.	Funds may arrange for medical service by 1. Free choice among panel of physicians or 2. Reasonable free choice among salar- ied physicians, or 3. District medical offi- cers, or 4. Combination of above methods.
<b>Financial Benefit</b>	20-50 times average daily wage. Min- imum of \$12 may be fixed.	None.	At least 20 times aver- age daily wage. Maximum, \$20.	None.	25 times average daily wage. Maxi- mum, \$13.50.	Fundal expenses Maxi- mum \$50.
<b>Contributors</b>	Percentage of wages from employer and employee.	Flat rate from em- ployer, employee, and state. Con- tributions of em- ployer and state pro- portionately in- creased for option- ally low-paid worker.	Percentage of wages from employer and employee.	Percentage of wages from employer and employee.	Percentage of wages from employer, em- ployee, commune, and state.	Percentage of wages from employer, em- ployee, and state. Employer's contribu- tion proportionately increased for ex- ceptionally low-paid workers.
<b>Insurance Car- rier</b>	1. District funds. 2. Other mutual soci- eties not operated for profit (establishment funds, nurses' funds, guild funds, etc.).	1. Cash benefit. (1) "Approved" soci- eties (Excluded em- ployees, establish- ment funds, friendly societies, etc.). Must be controlled by members and net ex- ceed 10% profit. (2) District "con- tributors' fund" if the outside soci- eties. 2. Medical and in- dustrial benefit rep- resentative. Insur- ance Committee in each unit.	1. District funds. 2. Other mutual soci- eties not operated for profit may be reorga- nized (establishment funds, registered and guild funds, etc.).	1. District funds. 2. Other mutual soci- eties not operated for profit may be reorga- nized (district funds, etc.).	1. District funds. 2. Other mutual soci- eties not operated for profit may be reorga- nized (district funds, etc.).	1. District local trade funds. 2. Other mutual soci- eties not operated for profit may be reorga- nized (district funds, etc.).
<b>Control of Cor- poration</b>	Employers and em- ployees' representa- tion 25 and 75 re- spectively.	1. Approved soci- eties. 2. District "con- tributors' fund" if the outside soci- eties.	Employers and em- ployees' representa- tion 25 and 75 re- spectively.	Employers and em- ployees' representa- tion 25 and 75 re- spectively.	Employers and em- ployees' representa- tion 25 and 75 re- spectively.	Employers and em- ployees' representa- tion 25 and 75 re- spectively.
<b>Government Supervision</b>	Local, state, superi- or and imperial in- surance offices.	In a few instances only.	Local and imperial offices under Ministry of Interior.	Insurance Committee in each unit.	Insurance Committee in each unit.	State Social Insur- ance Commission.

## Correspondence.

## TREATMENT OF HIP FRACTURES: A RE-JOINDER.

Boston, Nov. 22, 1916.

Mr. Editor:—

The evening of November 15 I spent, as it chanced, going over the chapter on hip fractures in a book of mine, published in 1910, trying to shape things up for a new edition, for I think I have learned something about this subject in six years. The next day I chanced to open the JOURNAL at Royal Whitman's most recent eruption.\*

I find little in it, save the curiously vituperative phrases heard before, often; not very interesting.

I take it we are all trying to find out how to treat hip fractures for the benefit of the patient; it is not apparent that such letters as Dr. Whitman's help much toward this end.

It is alleged that I am "obsessed" with the matter of impaction. Considering the fact that I have never advocated impaction in more than the rather small proportion of hip fractures that are loose or hopelessly displaced, "these seem harsh words!" Might one not say that a man who advocates abduction as the treatment in all hip fractures, without discrimination as to lesions present, and without x-rays, even, might have to defend himself against a charge of obsession?

There can be no doubt *today* of the vast prognostic difference between real fractures of the neck of the femur and those of the "base of the neck"; the trochanteric type. Can any one who talks treatment or results, publish alleged data without knowing what he has been dealing with, and "get away with it?"

So far as I could trace my cases, I have published them, and there have been a not inconsiderable number. I do not believe that artificial impaction solves the question of, or is indicated in, more than a minority of cases. In this minority it seems to have worked well. So far, I do not believe that abduction really locks the fracture, whether by leverage on the acetabular rim or by capsular tension (it is horribly hard to follow an allegation that is so inconstant), or that any effective locking can be maintained for the weeks necessary for consolidation.

The abduction position is desirable because it obviates undesirable muscle-contractions. It did not wait for Whitman to make itself heard, or practised.

The only point I have made in regard to hip fractures is that impacted fractures fare far better than those in which the impaction is absent; that the lacking impaction may be produced artificially; that cases of hopeless distortion, in neck fractures, may be reduced by manipulation, then locked by impaction; and that all these cases may thereafter be treated as one would treat an ordinary case, *acetabulantly* impacted! This sounds, I think, like a conservative statement, and it corresponds with my practice.

Since I came to this point of view, I have had far better results; excellent results, considering the class of cases presented! If anyone can show better results in this restricted class of cases, then I shall ask opportunity to see how he does it. But if anyone lumps *all cases of hip fracture together*, including all the "extracapsular" cases, and shows no x-rays, either of primary lesions or of end-results, then I shall feel justified in asking for actual data before opening a discussion.

Everyone knows that hip fractures occasionally show marvellously good results. Most of the cases of this sort I have found to be of the "trochanteric" type. These cases almost take care of themselves; with a nurse!

\* The customary notice of bombardment by writer or editor was not observed in this case.

What I want to know is, what becomes of the cases of *true neck fracture without impaction, or with extreme rotation*? These cases are the problem. Ordinarily treated, they do not do well. I have a string of cases that have done well under my scheme of treatment.

Will Dr. Whitman "come across" with cases demonstrated to be of *this type* with better results? I care nothing for the unclassified cases with alleged good results. Maxwell had more of these than Whitman has, I think.

This problem is larger than Dr. Whitman or myself. It involves the welfare of hundreds of patients. The question is not one of dialectics or abuse, but of facts. The question is purely as to what we should do with hip fractures, of the neck proper, in which there is no impaction, or in which impaction has occurred in such a way as to promise no real use of the limb after consolidation. I care nothing for the decision as to other types of fracture, types which do not do badly under any form of handling. The question concerns only this restricted type of fracture of the femoral neck.

F. J. COTTON, M.D.

## THE DOTEN BILL: ITS GRAVER ERRORS.

Boston, 9 December, 1916.

Mr. Editor:

I have read "The Doten Bill (House No. 1015)" as published in your JOURNAL Dec. 7, 1916, and also your very careful editorial, entitled "The Doten Bill." I agree with you that the proposition is one of grave concern for the medical profession. Out of an extended experience as a panel doctor in a "Kranken-Kasse" in Vienna, under the Austrian Act, let me try to answer the two questions you submit for the consideration of the profession.

1. Will health insurance improve the public health?

2. Will it improve the condition of those who have invested so much time and money in order to acquire the equipment necessary for the practice of medicine?

I answer "yes" to both questions, providing a health insurance act is properly drawn and administered.

If drawn and administered without due regard for the equities of all the parties concerned, my answer is emphatically "no."

A third question naturally follows: Is the Doten Bill drawn with due regard for the equities of all the parties concerned? Emphatically "no."

Finally, could the Doten Bill be so amended as to conserve the equities of all, without destroying its essence? "Yes."

It is a weakness of human nature, that it tends to follow a bell-wether. This may be predicated of the upper stratum, as well as of the mob. Previous to 1870 our silver, our jewelry, our toys, were tawdry were they not made in France. Bismarck demolished this idea when he confederated the German States, and thenceforth nothing seemed of value which carried not the trademark "Made in Germany." We have had German efficiency and organization dinned into our ears so constantly that we have lost the sense of other values. We have not stopped to consider that the cases are not parallel; that in Germany, where the individual is subordinated to the State, a certain efficiency and organization may produce a certain result, whereas in the United States, the individual being guaranteed "life, liberty and the pursuit of happiness," and the State resting on his consent, the application of German efficiency and organization may produce chaos. *Quod sit demonstrandum.*

Be that as it may, it is evident that the proponents of health insurance in America have fortified themselves by tracing health insurance to its source,—

the German Act,—and are arrayed with a mass of German statistics with which to confound the opposition. Now it is proverbial that statistics lie, and in this respect Germany is not in the bush league. Probably nowhere, however, are statistics and facts more at a variance than on the subject of health insurance. They point out, for instance, that since its inauguration, ten years have been added to the life of the average workman. This is important, if true, but the question arises, how much credit for this gain should be given to the medical profession for its triumph over pestilence and epidemics in general, how much to improved industrial conditions, rather than to the actual working of the insurance act? How unfair, for instance, to credit the drop in diphtheria mortality to the insurance act, when it belongs to antitoxin. What the Germans do not tell us, however, is that, in spite of statistics, the city of Vienna has more tuberculosis, in proportion to its population, than any city in the world; that the insurance act has been the cause of the worst kind of insurance and medical politics imaginable; that only the strong arm of the law has prevented its disrupting the medical profession; and that in the average "Kranken Kasse" diagnosis and autopsy are the things desired, recovery being a calamity.

Now the proponents of these American bills, either do not know these things, or they ignore them. In either case they are riding to a fall. They have adopted the high sounding slogan that "sickness is the cause of an enormous percentage of loss in industrial efficiency," and in so doing, they start their campaign with a fallacy, the one known to logicians as the fallacy of the consequent. They have inverted antecedent and consequent. Their slogan should be "Industrial inefficiency causes many serious conditions, among others a great deal of sickness." This formula gives us an opportunity to overcome two evils, instead of one. Political economy teaches us that intensive production in over-populated communities, while withholding natural resources, brings with it the law of diminishing returns, and eventually poverty and sickness. It teaches us that the remedy is emigration to less settled districts, and the opening up of the natural resources of these districts to correspond with the law of supply and demand, whence will flow health, wealth and happiness. Let us treat the effect, sickness, but let us not ignore the cause, industrial inefficiency. To those with Teutonic leanings, who doubt that this is the remedy, I point out that Germany, with her population pressing on the soil, saw the solution in emigration, and demanded her "place in the sun." What better proof is needed that, standing alone, health insurance was ineffective?

This somewhat lengthy preamble brings me to the Döten Bill. Let me ask its proponents to state without equivocation, whether it is a charity or a business proposition? If it is a charity, which I understand they deny, all must admit that it covers a multitude of sins. If it is a business proposition, conceived in the interest of business efficiency, let us be business-like about it. The bill, as drawn, is defective. I quote from your editorial, Mr. Editor, "As to the manner in which medical service is to be rendered, the bill is very nearly silent." Let me add that the silence is almost golden.

Let me hasten to dissipate the idea that I am a pessimist on the subject of health insurance. On the contrary, I am an optimist. My difference with the proponents of this bill is not one of substance, but only of form. I agree with their principle, and disapprove of their method. I do so, because while this matter is still *sub judice*, discussion may be valuable.

From time immemorial the physician has had an abiding faith, his share of hope, and, above all, an abundance of the greatest of these, charity. In its sweet name, no real physician has ever been called

in vain. History abounds with anecdote showing that the physician, depraved beyond hope, lost to all other emotions, still responds to the touch of charity.

But when we come to inject cut-rate methods into the practice of medicine, in the interest of business efficiency, we make the good doctor careless, the bad doctor worse, and purchaser will find that the goods delivered are not the ones he ordered. Under these circumstances, *carveat emptor*. The history of the German and British Acts; and of contract practice in our own country, shows conclusively, that this is the rock upon which they all foundered.

Let me put it another way. I agree with the proponents of this bill that public health is a purchasable commodity, just as carrots, beets and eggs. But the moment we say a thing is purchasable, we predicate further, that it has an exchange value, better known as the market price. When I agree to the premise, I do so only providing that it is followed to its logical conclusion. Let us say rather, that public health is a purchasable commodity, but only at its market price. Can this market price be determined? Easily, as I shall demonstrate by substituting a clause for one already in the act.

Are the proponents of this bill ready to pay the market price? "Ay, there's the rub." Yet it must be brought home to them, that if health insurance in America is to be a success, which all admit is questionable abroad, it must rest on a foundation, whose cornerstone is a fair fight and no favor.

A thorough analysis of the value of the Döten Bill would require the services of a mind with a legal turn, to which was added the gift of prophecy. Certain errors in it, however, are so outstanding as to be amenable to the law of common sense. Let me confine myself to two of them, for as they do not or do exist, so this bill is good, or no stronger than its weakest clause.

1. Legislation without representation is tyranny.

This is the first error, and may be called a geometrical one. The proponents of this bill have based their calculations upon the triangle: State, employer, and employee. I submit that all the equities of the situation call for a new survey, with calculations based, literally and metaphorically, upon the square. For, after all, this is a four-sided proposition: State, employer, employee, and organized medicine, with its allied branches.

The bill, as it stands, calls for three commissioners, political appointees, hence bending with the gubernatorial breeze, who shall delegate to themselves powers so plenary that the Czar of all the Russias might well be envious. These powers are so elastic, that they outstretch the proverbial imagination. One of the powers, so delegated, is sufficient to acquaint organized medicine with an entirely new conception of itself. I speak of the right to make contracts with physicians, dentists, etc.

At a stroke of the pen, we are converted from a time-honored profession into a time-serving trades union. We shall have joined the swelling ranks of Labor. We shall have qualified for the Labor Day Parade, and shall be expected to find our proper place in the alignment between the Steamfitters' Union and the Master Carpenters. And consider the clauses, for instance, each one of us hustling for a job, underbidding one another, our motto, "*occupat eubica extremum*," or the devil take the hindmost. Perish the thought! Have I a phobia when I think of these things? No, because to me they are stern realities. I know because I have seen them. Therefore, I say to organized medicine, while there is still time, "Awake!" Its very minimum demand should be for a representative on this board of commissioners.

He should be a man holding the degree of Doctor of Medicine from an A-plus medical school, and be elected for the position by and with the approval of the Massachusetts Medical Society.

No matter what his attainments, we can never be quite as well represented by one who does not hold this degree.

2. The bill as drawn is unconstitutional. In the first place, it is in conflict with a law which is already on the statute books. I refer to the "Medical Practice Act." Like it, or not, this law has certain effects. One of them is that it recognizes no discrimination; before it all physicians are equal. It assumes that physicians who have been approved by it are honest men, until it finds out otherwise. It does not place the burden of proof on these physicians. Having approved these physicians, it authorizes them to pursue their legitimate activities anywhere within the boundaries and confines of this Commonwealth. This is an inalienable right.

Now along comes the Doten Bill, embracing 70% of the population, and says to the physician, in effect, if not in words, "Your activities are to be curbed. Henceforth they must be parochial. Your territory is to be cut up. Later on, you will be told where you may and may not practice."

Clearly a violation of his constitutional rights, and of the dentists, pharmacists, nurses, hospitals, etc., equally. These are all equal before the law. Not satisfied with this parochial restriction, the Doten Bill goes farther. Having converted the State into parishes, it allows any employer having 250 or more employees, under certain ambiguous conditions, to establish his own medical plant. Opinion may be divided concerning the advantages of voluntary group medicine. Personally, I favor it; but what this bill advocates, in this particular, is compulsory group medicine—a horse of another color. It is clearly unconstitutional. It makes no difference, that by collusion, the State, a given employer, and his 250 employees, agree to hire a certain group of physicians.

This is an illegal combination restraining professional activities. The effect is class legislation in that it discriminates in favor of some, and against others by exclusion. Any compulsory contract under the Doten Bill is open to the same objection. Consider the effect in practice. I have had a patient who works for a large dry goods house; have had him for years. This bill takes him away from me and gives him to a group of physicians of whom he knows nothing. After a while he makes up his mind to work in the shoe business. The first group loses him to a second. With 70% of the population falling under this bill, private practice receives its death blow. I do not, however, believe, that as drawn, it will pass muster before the Supreme Court at Washington.

#### THE REMEDY.

The Doten Bill, properly amended, is a good bill. As drawn and published, it is greater than the State. This should not be. The State considers all physicians equal. The Doten Bill savors too much of Prussianism, of "*L'état c'est moi*." I recognize the fact that some sort of a disciplinary body will be necessary to govern the conduct of organized medicine in its relation to this act. Its construction I leave to others. I feel that the proponents of this bill, having shown such a tireless energy in the cause of humanity, may welcome some one else doing a little thinking. The field they have had to cover was enormous; the wonder is that they have done it so well. I am sure that they have often been discouraged in their work by the willingness of organized medicine "to let George do it."

I have never agreed with organized medicine in its policy of "*laissez-faire*." It has kept us apart from our fellow man. It has made simplicity mystery. At the end of this letter I append a substitution to be known as Part 2, Section 4, to be substituted for Part 2, Section 1, in the Doten Bill as published. This, with provision for medical representation on the Board of Commissioners, will conserve the equi-

ties of all concerned, and will not destroy the intrinsic value of the bill.

On the eve of this vital legislation, which will undoubtedly affect posterity, let us start aright, so that another generation, opening with the golden key of Thought, the jeweled box of Memory, shall arise and call us blessed.

#### PART 2.

Section 4. (To be substituted).

*Medical Service.* The carriers shall pay for such medical, surgical, and nursing aid at a rate, never lower than the fixed minimum, nor in excess of the fixed maximum rate, to be determined by the Massachusetts Medical Society and the various governing bodies of its allied branches. These fixed rates are for the purposes of this act, and are not to be construed as a free list for persons not carried under it. And further, the carriers shall allow the carried, freedom of choice in the selection of his medical, surgical and nursing attendants, provided only, that such attendants are licensed to practice their professions in this Commonwealth; and further, compulsion by the carriers, in this matter of choice shall be construed as a violation of this act, and upon conviction, such violation shall be punished by a fine of \$100, or one year in prison, or both. All other parts, sections, or clauses, in conflict with this section, are to be eliminated from this act.

Very truly yours,

JOHN J. HURLEY, M.D., F.A.C.S.

#### SOCIETY NOTICES.

NEW ENGLAND PEDIATRIC SOCIETY.—The forty-fifth meeting of the New England Pediatric Society will be held in the Boston Medical Library, Friday, Dec. 29, at 8.15 P.M.

1. Report of Council and nomination of officers.  
11. The following papers will be read: 1, Case Report, Wyman Whittemore, M.D., Boston; 2, "Some Observations with Sour Milk Feeding," C. K. Johnson, M.D., Burlington, Vt.; 3, "Difficulties in the Diagnosis of Diseases of the Hip-joint," A. T. Legg, M.D., Boston; 4, "Should All Milk be Pasteurized?" Richard S. Eustis, M.D., Boston.  
111. Election of officers.

Light refreshments will be served after the meeting.

A. C. EASTMAN, M.D., *President*.

RICHARD M. SMITH, M.D., *Secretary*.

#### MASSACHUSETTS MEDICAL SOCIETY.

##### SPECIAL MEETING OF THE COUNCIL.

There will be a special meeting of the Council in Sprague Hall, Boston Medical Library, Wednesday, Dec. 20, 1916, at 11 o'clock a.m., to consider the proposed legislation by the Massachusetts General Court on Industrial Health Insurance. The attention of Councilors is directed to the "Doten Bill," the full text of which may be found in the *Boston Medical and Surgical Journal* of Dec. 7, 1916, under "Miscellany." A special number of the *Journal*, devoted to Social Insurance, will be issued on Tuesday, Dec. 19, instead of on Thursday, Dec. 21, the regular date of issue.

WALTER L. BURRAGE, M.D., *Secretary*.

Boston, Dec. 13, 1916.

#### RECENT DEATH

DR. FREDERICK JAMES SANBORN died at his home in Spencer, November 20, aged 55 years. Dr. Sanborn was a graduate of the Bellevue Hospital Medical College in 1883, and joined the Massachusetts Medical Society in that year, having a residence in Holden. He had practised in Spencer for about 30 years.

### THE DIAGNOSIS AND CLINICAL CHARACTERISTICS OF GOUT.\*

BY JOSEPH H. PRATT, M.D., BOSTON.

"THE gout affords a striking proof of the long experience and wary attention necessary to find out the nature of diseases and their remedies. For though this distemper be older than any medical records, and in all ages so common; and besides, according to Sydenham, chiefly attacks men of sense and reflexion, who would be able, as well as willing, to improve every hint which reason, or accident might throw in their way; yet we are still greatly in the dark about its causes and effects, and the right method in which it should be treated." So wrote William Heberden in his "Commentaries" in 1782.

Although more than a hundred years have passed since these lines were penned, and although notable advance in the knowledge of gout has been made by clinical, chemical and pathological studies, yet the statement of William Heberden holds true today, for "we are still greatly in the dark about its causes and effects."

The disease is known to be definitely related to a disturbance of the purin metabolism. The blood in gouty patients usually contains two to four times as much uric acid as is found in health. After feeding food rich in purins the increase in the uric acid output in gout com-

pared with that in health is generally delayed and diminished. In the intervals between attacks of gout the uric acid output on a purin-free diet is generally less than normal. The acute inflammation of the joints in gout is followed by the deposition of sodium urate in the affected parts. In chronic gout, large deposits of sodium urate in the subcutaneous tissue frequently occur, forming chalk-like nodules called tophi.

The recent discovery by Folin and Denis<sup>2</sup> of a trustworthy method for determining the amount of uric acid in the blood and its clinical application has renewed interest in gout. The studies of the past three years, made with the aid of blood analyses for uric acid, have shown that the writers and teachers of fifty to one hundred years ago knew more about gout and its clinical characteristics than many of those who have written and studied the disease in recent years.

The greatest confusion exists in the minds of many practitioners in America today regarding this disease and its diagnosis. In some parts of the country the diagnosis is frequently made in conditions that are not gout; in other sections there seems to be a skepticism in the minds of many practitioners regarding the existence of such a disease. In New England I have found that chronic gout, even when tophi occur, is often mistaken for rheumatism or arthritis deformans. Some physicians of large experience in the Middle Atlantic States assert that they see gout frequently. Inquiry has shown that they mistake typical cases of arthritis deformans for gout, and the swellings about the joints, and even Heberden's nodes, for gouty

\* Read at the Annual Meeting of the Medical Society of the State of New York, Saratoga Springs, May 17, 1916.

deposits. One writer has diagnosed as gout 34 cases of arthritis that came under his observation in private and hospital practice in New York during a period of only a few months. These included seven cases in women, in whom true gout rarely occurs.

At one health resort, judging from my experience, many patients who have no form of joint disease are told that they are gouty and that "their system is loaded with uric acid." Only one of the arthritic patients I knew who had been there brought back the assurance from his physician at the Springs that he did not have gout, and, singularly enough, he was the only one who actually did have it. In his case the existence of tophi removed all doubt regarding the correctness of the diagnosis.

One of the chief reasons for the widespread misconceptions regarding the symptoms and signs of gout is the rarity of the disease in this country. Leading physicians in New York, Philadelphia and Chicago have told me within the past two years that they see very few cases in either hospital or private practice. In a paper published by Dr. J. M. DaCosta<sup>3</sup> of Philadelphia in 1881 he says, "There is a belief that gout is rare in this country, and typical gout is certainly rare." Dr. Horatio C. Wood<sup>4</sup> of Philadelphia in an address delivered in 1897 made the following statement: "I have seen two cases of typical English gout corresponding to Sydenham's description, and only two. We do not have it in this country." This was apparent confirmation of the assertion made by Sir Dyce Duckworth<sup>5</sup> a few years earlier that "In the United States of America gout is practically unknown." Dr. Osler,<sup>6</sup> writing on "Aente Gout in the United States" in 1895, states that "the comparative infrequency of gout in this country is a matter of everyday comment." He described three interesting cases he had seen during the previous year in private practice, and stated that he had, during the session of 1894-5 in the ward, four cases of gouty arthritis at one time, which was a unique event in his hospital experience.

Dr. Osler was convinced that the disease was often unrecognized in the United States, and in his clinical teaching he impressed upon the students the importance of a careful search for tophi on the ears or about the joints in every case of chronic arthritis. As a result Futeher<sup>7</sup> was able to collect in 1902 from the records of Osler's clinic no less than 36 cases of gout that were admitted to the Johns Hopkins Hospital during a period of eight years. A later statistical study prepared by Futeher<sup>8</sup> for his monograph in Osler's "System" was based on a series of 92 cases of gout observed among 30,871 medical admissions.

I am convinced that chronic tophaceous gout is less common in hospital practice in Boston than in Baltimore. For years I have made an

examination of the ears for tophi a routine procedure and rarely have I found them.

This assertion is supported by the statistics of the Massachusetts General Hospital. In the medical wards, from 1821 to 1916, there were only 41 cases diagnosed as gout among the 199,518 patients admitted.

#### CASES OF GOUT IN THE MEDICAL WARDS OF THE MASSACHUSETTS GENERAL HOSPITAL.

YEARS	NUMBER OF CASES
1821-1870	2
1870-1880	6
1880-1890	5
1890-1900	9
1900-1910	7
1910-1916	12
1821-1916	41

In the out-patient department of the hospital from August, 1903, to May 15, 1916, among 298,000 patients admitted to all the clinics, the diagnosis of gout was made 42 times. This makes a total of 83 cases collected from the records of 497,518 patients.

The fact that more cases of gout have been treated in the wards during the past six years than in any decade prior to 1910 suggests that the disease has been overlooked in the past, but possibly the use of Folin's method for determining the amount of uric acid in the blood has brought more cases into the hospital for study and treatment during the past three years.

In view of the widespread errors regarding the symptoms of gout, it is interesting to see what the medical students were taught about gout in the early days of this country at the three leading medical schools,—the University of Pennsylvania in Philadelphia, the College of Physicians and Surgeons in New York, and Harvard in Boston.

From Benjamin Rush,<sup>9</sup> for many years the professor of medicine at the University of Pennsylvania, the students could have learned little about gout that was sound, for his well-known essay on this disease is filled with errors.<sup>10</sup> There is no evidence in this record of his clinical observations that he had ever studied a case of true gout. A few quotations will indicate what a range of symptoms was regarded by him as diagnostic of gout. "The great toe and the joints of the hands and feet are no more its exclusive seats," said Rush, "than the 'stomach is the throne of yellow fever.'" In short, gout may be compared to a monarch whose empire is unlimited. The whole body crouches before it. . . The gout affects the glands and lymphatics. It produced a salivation of a profuse nature in Major Pearce Buller, which continued for two days. It produced a bubo in the groin in a citizen of Philadelphia. He had never been infected with the venereal disease, of course no suspicion was entertained by me of its being derived from that cause. . . "Scrofula and all the forms of dropsy are the effects, in many

cases, of a disposition of the gout to attack the lymphatic system. . . "A distressing collection of air in the rectum, which renders frequent retirement from company necessary to discharge it, is, likewise, a symptom of gout."

Contemporary with Rush there was living and teaching in London William Heberden, whose writings on gout are as valuable to our generation as the one for which they were prepared. In his long and extensive practice it is said that he saw as much of this disease as any physician ever did, but Rush in his writings was uninfluenced by the opinions of Heberden, and even the masterful clinical descriptions of the disease by Sydenham had upon him no restraining influence. From a study of Rush's essay, the conclusion seems justified, in view of the high esteem in which he was regarded by men of sense, that true gout was practically unknown in the American colonies.

The teaching in Boston regarding gout was doubtless along the lines followed by James Jackson<sup>10</sup> in his text-book of a course of lectures on the theory and practice of physic prepared for the use of students at Harvard and published in 1825. In this the diagnostic features of gout are not clearly or fully described. The chief symptoms that distinguish the disease from rheumatism are not given, and no mention is made of tophi. It is certain that the students saw no cases of the disease, for, although the Massachusetts General Hospital was opened in 1821, the first case diagnosed as gout was not admitted until 1845. This was probably an example of tophaceous gout, but characteristic features of the disease, if they existed, were not brought out in the clinical record.

In the clinical lectures of David Hosack,<sup>11</sup> professor of medicine at the College of Physicians and Surgeons in New York, there is an excellent description of gout. It is evident from his statements that he had some personal knowledge of the disease.

In the middle of the last century the standard text-book on medicine was that of George B. Wood,<sup>12</sup> professor of medicine in the University of Pennsylvania. To his teaching must be attributed some responsibility for the diagnostic errors of his students and readers. He held that a condition which he termed nervous gout was increasingly common, having, to a considerable degree, superseded the old-fashioned gout. "I have no doubt," he writes, "that much of the neuralgia, now so prevalent, is only gout or rheumatism in the nervous form."

Many physicians still hold the false belief that an increased output of uric acid in the urine or the formation of the pink or lateritious deposit is characteristic of gout. This error is due in large part to the view commonly held thirty years ago that a pathological state allied to gout exists, a "half gout" as it was called, and to which Murchison<sup>13</sup> gave the name lithaemia. DaCosta, writing in 1881, said that in this country "lith-

aemia is most common, and if it be true gout it is pre-eminently the American gout." The "abundance of lithic acid (uric acid) or lithates in the urine," said DaCosta, "frequently coexists with signs of ill-assimilation of food, with aches and pains unaccompanied by any perceptible changes of the aching part." As the aches and pains of neurasthenia were attributed to "lithaemia" or the "American gout," whenever a deposit of urates formed in the patient's urine on cooling, it must have followed that this diagnosis was frequently made. As late as 1895 a leading clinical teacher in a paper on irregular or atypical gout said, "headache, migraine, depression of spirits, shooting pains, cramps, palpitation and vertigo are a part of the symptomatology of lithaemia."

In the same year there appeared the American text-book of medicine, which contained an article on gout as misleading in its teaching regarding this disease as anything that had been prepared for the American medical student since the days of Rush. Gout, the author asserted, was the most conspicuous manifestation of the arthritic diathesis, and a concise and accurate definition of the term was impossible. According to him, gout and nineteen other diseases, which are enumerated, are all dependent upon "a peculiar and ill-defined retardation of nutrition that constitutes the arthritic diathesis."

The false ideas regarding gout and the hypothetical clinical condition "lithaemia" were so deeply rooted in the minds of physicians that fewer facts and more fancies concerning gout were taught in America in the latter part of the eighteenth century than by Heberden in England a hundred years earlier.

The admirable article on gout in the first edition of Austin Flint's<sup>14</sup> practice, which appeared in 1866, can be appreciated at its full value only by one familiar with the false views so generally held at the time it appeared. Flint coined the term "uricaemia" to designate the excess of uric acid in the blood which Garrod had shown to exist in gout. The false teachings regarding "lithaemia" and the "uric acid diathesis" never crept into this text-book of medicine, which always remained a trustworthy guide to the student. In his last revision<sup>15</sup> he showed the critical scientific spirit which pervades all his writings in his brief reference to this subject. "The designation 'uric acid diathesis,'" he said, "is used by some physicians in a rather indefinite way to describe various morbid states, which may not at any time be accompanied by deposits of urates and in which there is no proof of an excess of uric acid in the blood."

This criticism of Flint regarding the "uric acid diathesis" was well founded, as recent studies made with the aid of blood analyses, have shown that there is no increase of uric acid in the motley group of disorders which were regarded by Murchison and his followers as due to "lithaemia" and "uric acid diathesis."

*Symptoms of Acute Gout.* The clinical picture of a typical attack of acute gout has been drawn so clearly and so accurately by Sydenham<sup>16</sup> that it should be read and remembered by every student of medicine. I will quote a portion of his description:

"The victim goes to bed and sleeps in good health. About two o'clock in the morning he is awakened by a severe pain in the great toe; more rarely in the heel, ankle, or instep. This pain is like that of a dislocation, and yet the parts feel as if cold water were poured over them. Then follow chills, and shivers increase. After a time this comes to its height, accommodating itself to the bones and ligaments of the tarsus and metatarsus. Now it is a violent stretching and tearing of the ligaments—now it is a gnawing pain, and now a pressure and tightening. So exquisite and lively, meanwhile, is the feeling of the part affected, that it cannot bear the weight of the bedclothes nor the jar of a person walking in the room. The night is passed in torture, sleeplessness, turning of the part affected, and perpetual change of posture; the tossing about of the body being as incessant as the pain of the tortured joint, and being worse as the fit comes on. Hence the vain efforts, by change of posture, both in the body and the limb affected, to obtain an abatement of the pain. This comes only towards the morning of the next day, such time being necessary for the moderate digestion of the peccant matter. The patient has a sudden and slight respite, which he falsely attributes to the last change of position. A gentle perspiration is succeeded by sleep. He wakes freer from pain, and finds the part recently swollen."

To show the accuracy of Sydenham's description of genuine acute gout as the disease is seen in America, I will give the description as recorded in the clinical histories of four patients seen within a year.

C. F., aged 49. Seen April 5, 1915. About 1895 he had acute inflammation of the great toe of the right foot. There was marked swelling, redness, and extreme tenderness. The pain was excruciating and continuous. Even the weight of the bed-clothes increased it. For three nights he got almost no sleep. Duration of attack, about two weeks.

J. T., aged 40. Seen August 5, 1915. First attack of "rheumatism" in 1907. It began in the wrists. They were painful, reddened, and swollen. A day or two after the onset, both great toes became greatly inflamed. They were distinctly swollen, very red and shiny. If they were touched he "had to holler." The pain was more severe during the night. He scarcely slept at all until six o'clock in the morning.

D. T., aged 55. Seen June 16, 1915. First attack of gout in 1900 in great toe of right foot. One day he felt a little lame. The following morning about 4 a.m. he awoke with very severe pain in the metatarsophalangeal joint. The joint was swollen to the "size of an apple" and was as "red as a beet." It

was a jumping pain and continued for three or four days. It disturbed his sleep. He thinks it was worse during the night than day. He was confined to the house six or seven days. Relief was obtained by rubbing about the inflamed joint, but the joint itself was exquisitely tender.

Mrs. A. McC., aged 58. Seen Oct. 3, 1915. In January, 1915, attack of acute inflammation in the right great toe. Confined to bed two weeks. Onset very sudden. Felt perfectly well the previous day. Awakened at 4 a.m. with "terrible" pain. When morning came toe was greatly swollen. It was 2 to 3 times the natural size and it became very red. By night the whole foot was purple. Pain severe for several nights. The severe inflammation lasted two weeks. The tenderness was so great that she became uneasy as soon as anyone approached within two or three feet of the bed, for fear that the joint would be touched or moved.

*Seat of the Affection.* It is a remarkable fact that the disease usually vents its first fury on the great toe. All authorities are agreed upon this. Sir Charles Scudamore<sup>17</sup> found, in an analysis of 516 cases of gout, that in 373 the great toe was involved, either alone or with some other joints, in the first attack. In Garrod's<sup>18</sup> experience in not more than 5% of the cases was the great toe not implicated in the first fit of gout. In later attacks of acute gout, and especially in the milder joint manifestations of chronic gout, the great toe may escape and the inflammation be less typical. Hence it is important to obtain an accurate description of the initial attack and to ask every patient suspected of having the disease if the great toe has ever been involved.

*The Character of the Inflammation.* The classical symptoms of inflammation—dolor, rubor, and tumor—are present. I have seen a typical attack of gout in the elbow mistaken for a phlegmon, and an operation undertaken.

The pain is intense, amounting often to torture, and its severity is of great diagnostic value. In rheumatism, the disease with which gout is usually confused, the pain is not so great, and rarely causes much suffering unless the affected part is moved. Watson,<sup>19</sup> in those fascinating clinical lectures that will never grow old, says that the distinction between the two diseases was described by a humorous Frenchman in this way: "Place," says he, "your joint in a vise and screw the vise up until you can endure it no longer. That may represent rheumatism. Then give the instrument another twist, and you will obtain a notion of the gout."

Your own Hosack emphasized the severity of the pain in a way that probably stuck in the minds of the young students in New York a century ago. Let me quote from his lecture on gout:

"Some compare it to the gnawing of a dog, the pressure of a vise, or the pain of the actual cautery; this probably is not far from the truth, judging from the anecdote I have heard of a man subject to gout. This man falling asleep,

barefooted, before a large fire, the fire fell, and a large coal found its way to his foot; half awake and half asleep, he cried out, 'There's that d—d gout again!' He at length awoke, when he found a large coal frying his great toe. The sensation of the two evils was probably the same."

The exquisite tenderness of the affected joints in gout has been recognized by all authoritative writers since the time of Sydenham, yet a professor of medicine in a New York school, as late as 1896, states in a paper on gout and rheumatism that in "rheumatism, particularly when a joint is acutely inflamed, there is usually more superficial or cutaneous tenderness than in gout!"

The occurrence of edema in the gouty part and the subsequent desquamation of the skin are characteristics of the acute attack that are emphasized by Garrod. The attack usually lasts many days, and sometimes for weeks. There is some fever at onset, but the temperature is rarely high. Profuse sweating, so common in acute rheumatism, is said never to occur in gout.

True gout rarely develops before the age of twenty, and the onset is more frequent between the ages of thirty and forty than during any other decade (Sendamore). Hosack pointed out to his students that the disease usually occurs after the thirty-fifth year. He contrasted this with rheumatism, which "generally appears between puberty and thirty-five, in the greatest vigor of life—gout after that period—so that we may say, where rheumatism ends, gout begins."

One should always be suspicious that an attack of acute febrile inflammation of the joints occurring after the age of thirty-five, in a person who has never had a previous attack of rheumatic fever, is not rheumatism, but gout. Acute endocarditis, which is such a common complication of rheumatic fever, does not occur in gout. Another aid to differential diagnosis is the frequent association of gout and chronic interstitial nephritis, and the rarity of acute rheumatism and chronic Bright's disease in the same person. Some of the cases of polyarticular gout I have studied have closely simulated rheumatism.

In the following case the correct diagnosis was not made by the eight or ten physicians who had treated the patient during the twenty-seven years that he had suffered from recurrent attacks of gout. All had regarded the disease as rheumatic fever. I did not feel sure of the diagnosis until I saw the swelling on his elbow, which presented the typical picture of a chronic gouty olecranon bursitis.

C. A. P., male, aged 57. Suffered from "rheumatic fever" severely from the age of 30 to 52. He still has occasional attacks and is much crippled.

The trouble began in the ankle. In the first attack, there was great swelling of the ankle and leg. The skin was tense, dark red and exquisitely

tender. For 3 or 4 years the inflammation never extended above the knees. The knees since then have been more frequently inflamed than any other part. The feet have been often involved, sometimes the instep, sometimes the outer side of the foot, but never the great toe. Nearly all the joints have been inflamed in several attacks. Once "the jaws and all the other joints of the body" were affected and "all the muscles except those of the eyes and mouth." In the last attack, which came on about two months ago, the whole right hand was involved.

On account of lameness rarely walks upstairs; in fact, has been able to take very little exercise. Formerly the knee and calf of both legs would swell. For three or four years he has had swelling of the left lower leg and left foot. The extent of the swelling depended on the amount of walking he did. For years has been unable to get down on his knees. For 20 years he was more lame than he has been during the past two years.

During the attacks there was marked swelling and redness of the joints and high fever. Exquisite tenderness was a striking feature. Sometimes he has had 25 pillows under him at one time. Pain usually worse about 8 p.m. than at any other time—and more severe during the night than during the day. On one occasion the pillow under his head was not touched for 24 hours owing to pain on moving his neck. Repeatedly laid up 2 or 3 months at a time; once confined to the house for nearly six months. Duration of last attack about ten days. Fever has lasted for 2 to 3 months. Heart never involved.

Seven years ago, a nodule the size of a split pea developed on the fourth toe of the right foot and projected above the surface. It ruptured and discharged material that looked like "chalk and thick mucilage, but not well mixed." For over a week his doctor came and scraped the ulcer "down to the bone." A sinus persisted several years.

About two years ago two nodules formed in the skin on the pinna of the right ear, two or three times the size of a grape seed, of whitish color, containing chalk-like material. Another physician was then in attendance, but he still adhered to the diagnosis of rheumatism after the tophi formed in the ear.

The left olecranon bursa has been distended with solid material for three years. Inflammation and distention were frequent for 10 years prior to that. For weeks at a time has had both arms suspended in slings.

For ten years has taken 2 grains of morphine a day. He acquired the habit in attempting to get relief from the pain. Has never been given alcohol to his knowledge. Up to two years ago, took alcohol freely.

*Status Presentis.* Patient is a tall, strongly built, fairly well nourished man. Muscles flabby. Subcutaneous fat abundant over the abdomen. No palpation of the knee or membranes. Lungs normal. Enlargement of the heart to the left. A systolic murmur replaces the first sound at the apex. Aortic second sound not definitely accentuated. Arterial hypertension. Blood pressure, systolic, 220; diastolic, 110. No tophi in the ears. On the inner side of the left elbow is a small sack filled with hard, irregular masses like pebbles. It projects about 2 cm. beyond the olecranon, and is about 3 cm. wide. Near this mass in the subcutaneous tissue of the elbow are

several similar nodular masses about the size of split peas. No deformity of the other joints.

The blood contained 2.1 grams of uric acid on a purin-free diet, but 72 hours after eating 160 grams of sweetbreads the amount had increased to 3.4 grams. The uric acid in the urine on a purin-free diet was abnormally low. The urine was free from albumin at the time of my examination, but tube casts were present.

In this case the severity of the pain, the tenderness of the affected joints, the redness and the great swelling, the age of onset, the alcoholic history, the freedom from endocarditis, the existence of hypertonia,—all were characteristic of gout and not of rheumatism.

Genuine gout is rare in women. All but one of my 21 cases of undoubted gout, in which the uric acid was determined in the blood, have been in males.

In this country the hereditary form of the disease is far less common than the acquired.

The influence of alcohol in causing gout was known to the ancients. A Greek poet described gout as the daughter of Bacchus and Venus. Fermented liquors are the chief predisposing cause. Only two of my patients were teetotalers, and nearly all had taken alcohol freely. Porter and heavy wines, especially port, predispose to gout. Possibly the freedom from gout in America is due to the fact that light beer and whiskey are the alcoholic drinks chiefly used. Gout was rare among the workers in Scotland and Ireland, where whiskey is the chief beverage, and at the same time extraordinarily common among a body of men in London called ballasters, derived from the peasantry of Ireland, who did heavy work in the Thames. These men, according to Budd,<sup>20</sup> drank two to three gallons of porter daily.

An excess of animal food and a sedentary life have long been known to favor the development of gout. The relation between lead poisoning and gout was first pointed out by Garrod. He recognized that lead alone did not powerfully predispose to gout, as women engaged in white lead factories, who often suffered from colic, rarely had gout. Our experience points to the same conclusion. Although gout is so rare, lead intoxications in their milder forms, are common. The manifestations of gout among workers in lead have been especially studied by Lüthje,<sup>21</sup> who describes a "lead gout" with a characteristic clinical course. The disease begins at a relatively early age and quickly involves many joints. The tendency to tophi formation and joint deformity is more marked than in ordinary gout.

The term *chronic gout* is given to those cases in which the attacks are frequent, and deformity or rigidity of the joints occurs. The signs of acute inflammation are less than in the acute disease, but the duration of symptoms is longer. In fact, suffering and disability may be constant. In chronic gout chalk-stones are apt

to form. They are not found in any other disease. Although the most common site is the helix of the ear, they are often observed on the fingers and toes. A microscopic examination of material from nodules thought to be tophi should always be made. The beautiful acicular crystals of sodium urate are easily demonstrated. The frequency with which sodium urate is deposited in the olecranon and prepatellar bursae is not generally recognized. Inflammation of these bursae is almost pathognomonic of gout. In many cases the olecranon bursa on each elbow becomes converted into a hard rounded mass several centimeters in size.

*Radiograms in Gout.* In chronic gout the x-ray is often an aid in diagnosis, as characteristic changes in the bones frequently occur in this disease. These consist of small dark areas on the plates, circular in outline, with clear, sharp borders. They are usually found in the epiphyses of the affected joints, especially of the fingers, and are due to the absorption of bone from areas in which sodium urate has been deposited.

*The Urine in Gout.* When a gouty patient is on a purin-free diet the uric acid output is often low in the interval between attacks, but rarely below the limit of normal, which is placed at .3 gram per day. This was known to Garrod, but the error is still widespread that gouty patients excrete large amounts of uric acid.

For the day or two preceding an acute attack there is a fall in the uric acid output below the usual level. This is followed by a marked rise early in the attack and a secondary fall.

*Uric Acid in the Blood.* The evidence is conclusive that the uric acid is usually notably increased in gouty individuals in the intervals as well as during attacks. The average amount in my 21 cases of genuine gout, irrespective of diet, was 3.7 mg. per 100 grams of blood. In 156 non-gouty cases studied by Adler and Ragle<sup>22</sup> the amount was 1.7 mg.

In a few cases of undoubted gout the uric acid in the blood was found to be within normal limits, but even in these cases on a purin-free diet it was never below 1.4 mg.

The sweetbread meal has proved of aid in diagnosis. The patient is placed on a purin-free diet and the daily output of uric acid in the urine determined. After having been on this diet for at least four days, the blood is analyzed for uric acid and 150 to 300 grams of sweetbread (weighed raw) are fed. The purin-free diet is then resumed. The blood of a gouty subject 48 to 72 hours after the sweetbread meal has shown in every case examined an abnormally high amount of uric acid, while in control subjects this was not found. It is not improbable that this rise in the uric acid content of the blood may occur in certain cases of nephritis and in other pathological conditions.

Recent investigations have modified previous

ideas regarding the excretion of exogenous purins, but it is a fact that the feeding to a normal person of food rich in purins, such as sweetbreads, is followed by a striking increase of short duration in the excretion of uric acid. In gouty subjects the increased output is usually delayed and diminished.

This disturbance of uric acid metabolism also occurs sometimes in nephritis and it has been observed by Pollak in chronic alcoholism.

Pain or acute inflammation in the joints developing a day or two after the sweetbread meal is very suggestive of gout.

The subjects of chronic gout, according to Friedrich Müller,<sup>23</sup> are more susceptible than normal persons to uric acid. Workers in his laboratory found that subcutaneous injections of diluted solutions of sodium urate produced stronger inflammation in gouty patients than in normal persons.

**Therapeutic Tests of Diagnostic Value.** The prompt relief from pain produced by colchicum in gout is so striking that many have asserted that this drug is a specific in gout. It is certainly an aid in diagnosis, as colchicum does not have such a marked effect in relieving the pain in acute rheumatism or in other conditions which may be confounded with gout. Salicylates rarely have any marked effect in controlling the pain of acute gout.

The relief from the severe pain of gout by atophan is even more striking than that produced by colchicum. Its value in diagnosis is probably less, as it often is of considerable aid in checking the pains of non-gouty arthritis.

## ANAPHYLACTIC ACTION OF GRAINS ON RESPIRATORY TRACT.

By J. A. TURNBULL, M.D., BOSTON.

IN this report I wish to demonstrate the cutaneous reaction, produced by proteids of wheat, barley, oats, corn and rice, and the anaphylactic action of the proteids of these grains, especially wheat, on the respiratory tract. I have taken wheat as a standard, on account of its frequent and common use in our daily diet. In my private cases, and in those of the out-patient clinic of the Massachusetts General Hospital, I have obtained reactions to wheat in one hundred cases.

The cutaneous tests are preferably made on the flexor surface of the forearm, keeping one and a half inches below bend of elbow, on account of hypersensitive area above this margin, area limited below to muscular part, above tendinous termination. When, from some cause, as in dermatological cases, this area is impracticable, I choose a clear surface, wherever it may be—arm, leg, back or abdomen.

Controls are always made on whatever parts tested; if using both arms for test at same time, controls should be made on each arm, as there are varying degrees of sensitiveness in different parts of the body, and corresponding areas; in many cases, for instance, the left forearm is more sensitive than the right. Suitable area is washed with alcohol 70%, with as little rubbing as possible.

Test material, whether in liquid or powder form, is applied to skin: linear incision, half centimetre in length, is made, at same time carrying proteid into the incised area. In making incision, I avoid drawing blood. In some cases, immediate hyperemia appears about incision, which is due to mechanical injury. This rapidly disappears before reaction from proteids takes place. Positive reactions appear in from two to twenty minutes, and are manifested by appearance of wheal, wheal and hyperemia, or hyperemia; many cases with onset of reaction, burning and itching sensations, in which patient is unable to locate till later the exact area of such sensations. My reactions are recorded from suspicious (S) to four (4) in comparison to control. Suspicious, represented by a slight hyperemia or elevation; four (4) being represented by wheal 1.5 centimetres in diameter, with or without hyperemia, or by hyperemia extending over an area of three centimetres,

with varying degrees of reaction between S and 4.

The following table shows skin reactions in cases in which grains produce anaphylactic respiratory disturbances.

TABLE I.

No.	WHEAT	BARLEY	OATS	CORN	RICE
1	3	2	2	1	4
2	1	0	0	0	0
3	4	0	8	3	0
4	2+	1	8	1	1
5	2	2	2	2	2
6	2	0	0	0	0
7	1	0	0	0	0
8	1+	0	0	0	0
9	1	0	0	0	0
10	3	1	8	1	1
11	1	0	0	0	0
12	3+	3	0	3+	8
13	3+	4	2+	1	0
14	3+	4	2+	1	0
15	3	4	0	0	0

Reference to the above table shows wheat giving the highest percentage, and with few exceptions the greatest reactions of the grains, which may be due to sensitization by its frequent use.

Taking wheat as a standard, represented by 1, ratio of reactions of grains in Table I is as follows: wheat 1, barley .46, oats .4, corn .4, rice .46.

Examination of Table II shows that in these cases, with few exceptions, the individual proteids of wheat do not give as marked reactions as wheat proteid, nor by the reactions could we decide that any individual proteid is a cause of the anaphylactic reactions. I believe that the anaphylactic reactions of wheat are due to its combined proteids rather than to any individual proteid. Disturbances of the respiratory tract, produced by proteids of grain, in series of cases, Table I, I classify as follows:

1. Vasomotor Rhinitis.
2. Cough.
3. Bronchitis.
4. Asthma.

I will now enumerate the subjective clinical

symptoms in the cases of Table I, according to classified respiratory condition.

No. 1. Male, baker for nine years; four years ago began with frequent and severe attacks of sneezing, profuse serous nasal discharge, lachrymation, itching of eyes, nose and throat. Symptoms all increased when working in bakery. Omitted bread and boiled cereals from diet, all symptoms stopped at once; bread and cereal added to diet, return of all symptoms.

No. 2. Male, baker for twenty years. For ten years, frequent attacks of sneezing, nasal discharge, lachrymation. Bread omitted from diet, free from all symptoms; bread added to diet, return of all symptoms.

Nos. 1 and 2 were desensitized to wheat. I prepared a watery extract of flour by adding water to flour, keeping in a cool place for twenty-four hours, then filtering; to watery filtrate was added alcohol to make 14% of whole solution. This stock solution gave four (4) skin reaction. By making a series of dilutions of stock solution, testing these dilutions, 1-1000 gave suspicious reaction. Of this 1-1000 I gave five minims first dose, giving dose every third day, gradually increasing dose, according to reaction; after second dose, both cases were relieved of all symptoms. No. 1 received seven doses; No. 2 four doses; treatment then stopped to see how long their immunity would continue. In both cases there was return of all symptoms two months after stopping treatments.

No. 3. Male, baker, worked three years in a bakery; did not work with flour until one year ago. Two months after working with flour began with frequent attacks of sneezing, free watery nasal discharge; omitted bread and corn from diet. Continued his work in bakery, working with flour, without symptoms.

No. 4. Male, baker, worked in bakery at intervals for ten years. Last two years when going into bakery, or works with flour, or in a room where anyone is working with flour, attacks of sneezing,

TABLE II.

SHOWING SKIN REACTIONS WITH WHEAT PROTEIDS AND THE INDIVIDUAL PROTEIDS OF WHEAT.

No.	WHEAT PROTEID	ARTIFICIAL WHEAT PROTEIN	WHEAT UNFRACTIONATED	WHEAT PROTEOSE	WHEAT GLOBULIN	GLOBIN	CATEXIN	PROTEID DECOMPOSITION	ALBUMEN AND PROTEOSE
17	4	3+	2+	3	4	0	1+	0	1+
18	12 3+	1+	1	1+	1+	1+	2	1+	0
19	12 3+	1	0	0	1	0	1	0	1+
20	1+	2	0	0	0	0	0	0	0
21	1	1	0	1	0	0	0	0	0
22	1+	2	0	0	1	1	1	0	0
23	3+	0	1+	0	1	0	0	1	0
24	12 3+	0	1+	0	0	0	0	0	0
25	1+	1	1+	0	1+	0	0	0	0
26	3+	0	0	0	12	0	0	2	2
27	3+	2	1+	1+	1	0	0	0	0
28	3+	0	1+	0	1+	0	0	1+	2

profuse serous nasal discharge, lachrymation, itching of eyes and nose.

No. 5. Male, baker, twenty years; for ten years frequent attacks of sneezing, nasal discharge; stopped using wheat bread, and boiled cereals, symptoms were relieved.

No. 6. Female, servant, frequent attacks of sneezing, watery nasal discharge, headaches for one year. Omitted bread from diet, symptoms stopped at once. Smallest piece of bread would cause return of symptoms.

No. 7. Female, seamstress, for one year frequent attacks of sneezing, watery nasal discharge, itching of eyes and nose. Bread omitted from diet, all symptoms stopped.

No. 8. Female, clerk, frequent attacks of sneezing, watery nasal discharge; symptoms began one year ago, with an acute cold. Omitted wheat from diet, symptoms stopped. This case probably began as acute bacterial infection of upper respiratory tract, with the bacterial proteids of acute cold, added to a system which was, no doubt, sensitive to wheat. Symptoms were produced as greater amount of a foreign proteid was added to an individual sensitive to foreign proteids. Bread omitted from diet, thus lessening the sensitive proteid. Symptoms were stopped.

No. 9. Female, stenographer; for three years sneezing, watery nasal discharge. By stopping wheat, one of the foods she was sensitive to, symptoms were relieved.

No. 10. Female, aged 60, coughed for two years, worse at night; cough so frequent and hard at night as to disturb sleep. Nose blocked most of the time. For twenty years frequent attacks of sneezing, watery nasal discharge, lachrymation. If working with flour, sneezing so severe, nasal discharge so profuse, would have to wrap towel about nose and mouth. Bread and boiled cereals omitted from diet; all symptoms stopped, nose clear, no cough, rest unbroken.

No. 11. Female, housework; for twenty years cough and bronchitis, shortness of breath, tired easily, no ambition. Wheat one of articles excluded from diet; in two weeks cough stopped, lungs clearer. Patient expressed herself as "able to take a deep, clear breath," does not tire easily, more ambition, able to do work she has not been able to do for ten years.

No. 12. Male, colored, ate barley soup, in a few hours, coughing, sneezing and shortness of breath.

No. 13. Female, school-teacher; asthma for five years. Bread and boiled cereals omitted from diet, free from asthma. Can bring on severe attacks by eating bread.

No. 14. Male, worked in biscuit factory for thirty-four years. Six years ago began with cough, which increased in frequency and severity; for three years asthma, during this time attacks have increased in severity and frequency—attacks every night. If entering biscuit factory, attacks come on at once, so severe cannot stay in factory. Change of climate without benefit. During rainy weather, attacks were continuous; as patient expressed him-

self,—"would nearly die." Bread, barley, oats, corn, eliminated from diet; attacks were relieved at once. With few other foods, to which he is sensitive, eliminated from diet, he is free from asthma, even during stormy weather. This man is now running his own bakery.

No. 15. Male, oil dealer, asthma for two years. Wheat bread eliminated from diet, attacks stopped at once. This case expressed himself as feeling better in one week than he had for three years. After avoiding bread for two weeks, he ate six slices of bread in two days, which brought on hardest attack of asthma he ever had. Omitted bread from diet. No return of asthma.

Nos. 1, 2, 3, 4, 5 and 14 all worked in bakeries, where considerable proteids entered by respiratory tract. In these cases the subjective symptoms developed at various periods from two months to twenty-nine years, after beginning work in bakeries. All these cases ate large amounts of bread. This, with the extra amount of wheat proteid, entering by inhalation, the toxic proteid was increased to more than these patients could assimilate without producing symptoms. By omitting from diet, bread and boiled cereals, to which they were sensitive, thus lessening the proteids which were anaphylactic to them, these cases were able to continue with their work in bakeries without disturbances of respiratory tract, thus showing they were sensitive to wheat, entering by gastrointestinal tract. With bread eliminated from diet, the amount which gained entrance by inhalation produced no anaphylactic subjective symptoms.

In all other cases, working at different occupations, the foreign proteids gained entrance only through the gastrointestinal tract.

I have shown by these cases that the proteids producing anaphylactic reaction, enter by (1) gastrointestinal tract, (2) respiratory tract.

Boiled grains gave a greater skin reaction than raw grains. Those cereals prepared by extreme dry heat, 300-500 Fahrenheit were changed by the heating process in such a way that their proteids were rendered non-anaphylactic to many individuals. Some cases show skin reactions to these high-heated, prepared cereals, and in these cases anaphylactic effects are produced by ingestion of these prepared cereals; which shows that high, dry, heated cereals do possess anaphylactic properties which are manifested in some individuals.

In some cases, which do not show skin reaction to high-heated prepared cereals, anaphylactic results can be produced. A series of cases giving wheat reactions were tested with yeast; in no case was the reaction obtained. One would thus form the conclusion that the yeast which enters in the making of bread has no anaphylactic action.

My series of pollenosis cases showed skin reactions to grain as follows: wheat 100%, barley 66%, oats 64%, rice 82%, corn 90%. On the other hand, not all grain cases showed skin

reactions to pollen of trees and plants. Many of my pollenosis patients who avoided bread and boiled cereals, and used as substitutes those high, dry-heated prepared cereals, to which they were not sensitive, found their symptoms diminished. Pollenosis cases were desensitized in less time, when eating these prepared cereals to which they were not sensitive.

In my early work with grains, I first used a watery solution. Later, my testing materials were prepared by adding water to flour, letting stand for twenty-four hours on ice, then boiling for one hour, again adding water, setting aside in a cool place for twenty-four hours, then filtering and allowing the watery filtrate to evaporate to dryness, and reducing it to powder.

I am now using grain proteids prepared by R. P. Wodehouse of Laboratory of Plant Physiology of Harvard University.

#### CONCLUSIONS.

Proteids of grain have a distinct anaphylactic action on respiratory tract in some individuals.

This anaphylactic reaction manifests its action on different parts of the respiratory tract in various ways. The entrance of these foreign proteids is by the gastrointestinal and respiratory tracts. Heating has effect on proteids; boiling increases their action. High temperatures of 300-500° Fahrenheit will destroy anaphylactic properties of these proteids for many; but even after 500° Fahrenheit for a half hour, there remains an anaphylactic proteid to which some are sensitive.

The cutaneous test is a valuable means of diagnosing the foreign proteids to which individuals are sensitive.

#### FORSYTH DENTAL LIBRARY AND MUSEUM.

THE trustees and director of the Forsyth Dental Infirmary for Children announce that at their meeting in October, 1916, a new department was established, to be known as the library and museum. In an institution composed of so many departments, this branch of dental progress is liable to be overlooked. The new library and museum are intended for preserving the results of experiments and discoveries made and of work done at the institution. For the development of this project, assistance is needed. Physicians and dentists are, therefore, cordially invited to contribute to the library, past volumes or numbers of dental journals, and any pathological specimens having reference to the aural cavity. For these, permanent acknowledgment will be given. Every assistance and cooperation will be welcomed in the effort to make this library and museum, like the institution which houses them, of unique value. Suggestions will be gratefully received by the trustees, director, librarian and curator, and information will be gladly furnished.

## ROUTINE MENTAL TESTS AS THE PROPER BASIS OF PRACTICAL MEASURES IN SOCIAL SERVICE: A FIRST STUDY MADE FROM 30,000 CASES CARED FOR BY 27 ORGANIZATIONS IN BOSTON AND SURROUNDING DISTRICTS.\*

BY HELEN M. WRIGHT,

*Social Worker, Psychopathic Hospital, Boston.*

#### PART I.

#### THE NEED FOR SOCIAL AGENCIES TO STANDARDIZE THEIR USE OF MENTAL TESTS.

IN a brief discussion of social service, which was included in a reading before the American Medical Association of June, 1913, Dr. Southard of the Boston Psychopathic Hospital said, "Progress should be made in every community to determine the dimensions of the social problem as it affects the psychopath."<sup>1</sup> To this end the social service departments of the psychopathic hospitals and clinics are endeavoring to work. On the other hand, economists and social workers have yet to determine the dimensions of the problem of the psychopath, as he affects society. The purpose of this paper is to discuss particularly the latter phase of mental welfare work.

More and more often social agencies are trying to determine to what extent mental disorders are responsible for their particular problems. This knowledge is being sought by organizations attempting to prevent the evils undermining social welfare, as well as by those working to alleviate and improve poor conditions, whether for the individual or for the public. In the endeavor to get opinions on individual cases, these organizations are turning to the mental specialists, to psychological clinics and to psychopathic wards and hospitals, for the diagnoses which will indicate to them the best course of action to be pursued in their respective problems. During the fiscal year of 1913-1914 of the Psychopathic Department of the Boston State Hospital,<sup>2</sup> 679 patients from a total of 3054 admitted to the House and Out-Patient Department (or one in every four admissions) were known to have been sent at the instigation of court officers, churches, settlements, social service departments in stores, family rehabilitation, relief and child-caring agencies. This number shows an increase over the figures of the previous year, due, in part, to a wider knowledge of the Hospital among agencies, as well as to a more general understanding and acceptance of the purpose of the Hospital by the patients

\* Read at the Third Annual Conference on the Medical and Social Work of the Psychopathic Hospital, June 18, 1915. Being Contributions to the Massachusetts Commission on Mental Diseases, Whole No. 162 (1916.20). The previous contribution was by Mary C. Jarrett (1916.19, 161), entitled "The Intensive Group of Social Service Cases," THE BOSTON MEDICAL AND SURGICAL JOURNAL, Dec. 7, 1916.

themselves. But so far the patients sent by social organizations have been largely those whose difficulties or peculiarities have been so distinctly marked as to class them definitely as psychopaths,—a term which may be understood to include, in general, the epileptic, insane, feeble-minded and doubtful or borderline patients, and those persons with such other mental defectiveness as would result in their being distinguished as generally asocial.

If one should ask the organizations why these 679 patients were chosen to be given a mental examination, from many others who might have profited by it equally as well, one would find that there is no standardized system for making the decision. Some agencies dealing with the same type of individuals use the clinic and hospital freely, others but occasionally. Some, for example, feel that every unmarried mother should be carefully examined in order to procure a working basis for the plans for her future; others look only to the weeding out of the dependently feeble-minded, or the troublesomely insane mother. One thinks no plan for a dependent child should be made without first determining his mental status—and his intellectual characteristics; others, again, employ psychological examinations only to aid in securing custodial care for the feeble-minded children. This lack of standardization in the selection of patients to be examined is probably due not only to various opinions as to the importance or significance of such examinations, but to an unfamiliarity with the signs of beginning psychoses and borderline defect, on the part of the community, as well as social workers. But whatever the reason, it is true that the decision as to whether or not an individual shall be given such an examination, or even observation, rests much as did the question of investigation in the early days of organized charity,—upon the judgment of the unspecialized agent or authority in charge.

Social organizations now are in a transitional period with respect to their recognizing the importance of measuring, scientifically, the mental capacity of the persons for whom they undertake treatment. They believe theoretically that the need of an individual, whatever its nature, cannot be met without an appreciation of his physical, moral, economic and mental condition. They employ trained workers to investigate the economic and moral situations. The physician is turned to frequently, though not as much as he should be, for advice as to the physical condition, but the average society relies upon the understanding and judgment of its workers for the recommendation that a person be given a mental or psychological examination. Such a standard for the use of mental tests meets the need of the individual and of the organization in a varying degree, dependent upon the experience with psychopathic individuals and knowledge of psychopathic diseases

which the worker may have had. It also has the disadvantage of singling out certain persons as suspectedly defective, and the patient himself is apt to resent it.

There was a similar transitional period when Frederick Osanam, the founder of the St. Vincent de Paul Society,<sup>3</sup> Thomas Chalmers,<sup>4</sup> Octavia Hill<sup>5</sup> and other pioneer workers in organized charity and reform movements, urged investigation as the only scientific basis for rendering charitable assistance of any kind. At first an investigation was made very guardedly and very superficially by the societies then in a position to make one. As time went on, certain cases were inquired into carefully as a matter of principle, but others were put aside as "too sensitive to be investigated." "evidently all right" or "because the society was too rushed at that particular time to go thoroughly into the inquiry"; and many well-meant corrections, kindnesses and alms went astray their mark because of it. It was years before social organizations of every kind took up the battle cry of "knowledge first"; and now no efficient agency or institution feels itself capable of giving advice, aid or supervision to any individual without first obtaining, through the services of a trained social worker, if possible, an intelligent understanding of that individual's social, moral, and economic history and, to a limited extent, his physical condition. Why should not one's mental history and mental calibre be of equal importance and be obtained in the same manner, that is, as *routine*? It is fundamental in every situation.

At one time in the history of the development of philanthropies, *routine* was a word which was to be avoided. That was in the early days of public charity, when meagre relief was doled out without respect to person. With the turning of interest toward the individual,—which first prompted investigation,—the public has been shown the dangers of blind routine, and has appreciated the general efficiency of intensive work with persons. Organizations have become *social*, as far as individuals and their relation to each other are concerned; but as Dr. Southard has so often said, the interpretation of *social* should not be confined to work with individuals or local communities. It stands for *society*, for *mankind*, and its meaning can be interpreted only through work with large numbers, unselected, and so dealt with that fundamental principles may be discovered. There are but few organizations which give time for the consideration of the particular conditions of their clientele en masse. Those agencies which do are leading those which do not; they are promoting genuine reforms.

With respect to the immediate problems for which each organization is instituted, each recognizes its own function: the Juvenile Court to decide whether a child shall be sent to a correctional institution or to a training school for

the feeble-minded and defective delinquent, or given indefinite custodial care. The Family Rehabilitation Agency, to decide whether parents are morally and intellectually capable enough to warrant keeping the family together, supplementing its income and supervising its development. The Child-caring Agency must know which children shall be offered for adoption and which ones for merely temporary care, which ones with special training in early years may be made self-supporting and self-protecting, and which must always be supervised. Church representatives must decide which parishioner will be wisely helped quietly, and which will be injured by aiding him without first consulting those who have known him the longest. The social service worker in the store must know whether or not she shall intercede on the part of an employee for another trial, and should be ready to say whether the employee is passing through a period of a day or a month when he is physically and mentally irresponsible,—at which time he is probably called lazy, eccentric, and impertinent by his co-workers,—or whether he is actually taking advantage of his employer. The inevitable Homes for Dependent Women, with their large number of cases of illegitimacy and drunkenness, must decide the best method of collecting accurate data, which will be of value in the general study of illegitimacy and intemperance.

An organization usually realizes its own limitations in its case work, and when the conditions of a problem show that the limitations have apparently been reached, the organization is turning more frequently to the mental specialist for advice. But why not establish the mental status of the individual first, and plan accordingly from the beginning? Why wait until all plans have failed and the workers are thoroughly discouraged? Every exaggerated instance of mental defect or disorder is comparatively easy to detect, but it is the apparently normal person, ill-fitted to his surroundings and misunderstood, who suffers most by unscientific treatment. The following stories illustrate some of these misunderstood types which come to us:

A young woman, 37 years of age, socially diagnosed as "a neurasthenic, who thinks the churches and social agencies owe her a living" (the diagnosis of neurasthenia having been made by an unspecialized physician, who had been consulted), was dropped by all who had helped her for some time, and given the advice that she was able to work and should take care of herself. She had a disfiguring acne eruption on her face, and explained it to the Hospital as due to a slow poison which her friends and relatives had been putting in her food for a number of years past. She had been restless in her work, frequently changed her positions, and as time went on became so paranoid that in the early spring her acquaintances persuaded her to go to the Psychopathic Hospital. After three

weeks' observation, during which time a careful history of her early life and habits was obtained, the diagnosis of dementia precox was made. On her discharge from the Hospital, the nature of her illness was explained to a former employer, who agreed to give her work again. Her acne was treated at another hospital, and finally cleared up entirely. A change in lodging was made, good meals and exercise were planned for her, and very soon her life was proceeding without friction. Her work was so good that she was one of five women kept steadily employed during the dull summer season. She had established herself without financial aid from anyone, and by the end of the summer she had paid her debts from her own savings. In case she should have a return of the former symptoms, which unfitted her for work,\* she will be returned to the Psychopathic Hospital for another period, while her place will probably be held for her by her employer, who understands the situation.

A girl of ten, in a reform school, was a difficult one to place in any department of the institution. She was never malicious, was attractive and very likable, and in some respects did well in school, but she quarreled with the girls in one division and complained so much of the officer in charge that she was transferred to another. Her work was slack. In the kitchen she couldn't "get along with the cook" and in the laundry it was the supervisor. In the school-room, her excuse was the same. She "couldn't get along with the people" she lived with. Finally she was put in the farm cottage, but even there, though other troublesome girls had shown improvement, she showed none. At length she was given the much-sought task of "tending the cows." When the cows did not return at the usual time, an officer went in search, and down by the fence in the pasture, sat the child in tears, sobbing that she "just couldn't get along with those cows." An examination later showed mental defect, and the child was transferred to a school for the feeble-minded.

A "complaining, lazy" father of a family of six children had been the loadstone of agencies and employers for seven or eight years. After much time and money spent in finding new employment for him and furnishing the means of livelihood for his family, he was brought under observation at the Psychopathic Hospital and diagnosed as a general paresis. He was committed to an institution for the insane, and plans made for the family by the agency in charge. The long-disputed question as to whether the father was able to work, or should be made to contribute toward the support of his family, was removed.

Miss N., a plaintive little woman of 27 years, with an illegitimate child, had been helped by all the child-caring agencies and other agen-

\* It is believed by some that in cases of dementia precox the patient frequently goes through a period of many months—even years—before the attacks of dementia are repeated. (See Kraepelin.)

cies interested in the problem of the unmarried mother, but she gave endless trouble. She was either complaining of the persons who were boarding her baby, or, if keeping her child with her, Miss N—— found it impossible to care for the child and do the work required. For several years frequent changes had been made by the obliging workers, who tried to please her. Upon investigation, the history and references which she gave proved fictitious, and it was frequently found that she was untruthful about other things. Finally all these agencies "closed her case" and had no more time to give to her. It was at this point that the Miss N—— came one day to a new agency. From the Confidential Exchange report it was evident that she should be returned to one of the societies formerly interested in her, but as each in turn refused to assume any further responsibility for her, the new agency undertook the work, and attacked the problem from another point of view. The applicant was undoubtedly worn out physically. A rest was promised her upon her consent to have a physical examination. She was sent to the Psychopathic Hospital. The report from there showed an active process of gonorrhea, a generally weak physical condition, and a mental classification of moron. Her baby also had a gonorrheal infection. Both were sent to the State Infirmary for treatment, where the mother stayed for three months.

In each of the foregoing situations, the advice of a mental specialist and of a psychologist was needed to determine the real nature of the problem, which to the lay worker had appeared to be entirely social.

If a system were in use for uniformly securing mental and physical examinations, including the Wassermann test, many of the difficulties which agencies now face would be obviated. The lay worker has questioned the value of the use of mental tests, but psychologists and physicians claim that they yield important results, if used carefully by specialists. Various methods of examining have been proposed.<sup>1</sup> The Binet-Simon scale<sup>2</sup> and the Healy<sup>3</sup> tests have, perhaps, been most generally in use. With patients whose defect proved decidedly marked, the examinations by these two methods were helpful to the agencies employing them, but for the patients classified as doubtful or borderline, the "all or none" method of the Binet scale did not truly represent their ability.

The Yerkes-Bridges Point<sup>4</sup> Scale, which has been devised at the Boston Psychopathic Hospital, has there supplanted the Binet scale. To quote from a recent publication regarding it:

The Point Scale "has been constituted with a view to simplicity and uniformity of use for measuring a variety of the aspects of mental capacity. The scale consists of a single series of tests, all of which are supposed to be applied to the individual under examination. For each test credit is given according to the merit of the subject's response, and the name, Point

Scale, is fitting because the subject achieves a varying number of points of credit according to his mental ability. The method provides for the comparability of the measurements made on individuals differing in age, since a large number of the mental functions which are considered exist in varying degrees in all the individuals examined. Finally, the Point Scale contains in itself the provision for improvement and for increase in the value of its results, since the series of tests may at any time be thoroughly revised in the light of the results obtained, and since the calculating of norms will inevitably increase the possibilities of interpreting results and of exhibiting any given individual in his relations to any group or collection of groups in which he belongs, and in comparison with whose mental status he should be considered and treated.

"The present Point Scale is to be regarded as a preliminary to the development of a universally applicable scale."

For measuring the mental capacity of illiterate foreigners, special tests have been standardized by Dr. Howard Knox<sup>5</sup> of the United States Public Health Service, New York. Acting Assistant Surgeon Shier<sup>12</sup> of the United States Navy has devised a system which is said to be especially adapted for the examination of applicants at the recruiting stations. Because of the many forms of mental tests and the accompanying claims and criticisms as to their respective values, there has grown up a distrust of their having any practical use other than that of detecting the markedly feeble-minded. If that were their only virtue, they would still be of distinct service to many institutions.

Passed Assistant Surgeon Sheehan of the United States Navy says:<sup>13</sup> "Methods of testing intelligence have been in use in psychological laboratories for many years, but it is only of late that they have been applied to the practical problems presented in pedagogy and psychiatry. As a result of their widespread use in these fields, it soon became apparent that they might be utilized to advantage by the military service as a means of excluding defectives. Considerable work has been done in the endeavor to adapt them to this purpose.

Due to the fact that these tests have been claimed by the popular press, and even by technical writers as an exact means of judging the mental and moral mechanisms of any normal or abnormal person, they have come into wide use, and often by persons having little or no scientific knowledge. Therefore, their true value has been lost sight of through uncritical exploitation and mystification."

But, aside from detecting the feeble-minded persons, these psychological examinations also record the success or failure of an individual's performance of certain tests. When given carefully and under conditions which place the individual at ease, these results should be a fair representation of his ability to do these tests, and the data should form a basis for valuable comparison with the results of future examinations.

If such an institution as the United States Navy Recruiting Station can find the use of psychological tests, given under favorable conditions, useful, surely organizations dealing with the dependent, delinquent, and distinctly asocial individuals, should find the use of them equally valuable.

By securing the psychological and medical diagnoses of social patients, social organizations, as well as other organizations, would not lose sight of the needs of the individuals. The diagnoses should be but a step toward more intensive work for them, and should indicate to the agent, the tendencies in the patients to be guarded or repressed and those to be strengthened or supplemented.

If such examinations were required as routine by every agency undertaking to supervise for any length of time the life of a child or an adult, the applicant who now considers the suggestion of such examination an implication that he is insane or feeble-minded, would come to look upon the process as he would upon the test of scholarship or ability,—as an effort to rank him with thousands of other people,—or an attempt to obtain a register which would point out to him, as well as to his supervisors, his weaknesses and his strong points.

The applicant would come to welcome the technic which enables the clinic to detect in his younger children the early stage of the disease which caused his oldest child to waste away as a juvenile paretic. He would appreciate the explanation that one child should be watched and trained with more care than the others, in order to give him a chance to cope equally well with the vicissitudes of life; or even the advice that a third child needed institutional training or custodial care, or that he himself should have treatment for syphilis as a safeguard against general paralysis or total blindness in middle life.

But, aside from the applicant's appreciation of the system, the directors of social welfare propagandas and social agents would be alive to new situations, and would find themselves looking for new ways to handle old problems. The high grade feeble-minded girl would be detected before she were old enough to face for herself the danger of becoming an unmarried mother.

The son who shows signs of early deterioration which mark the progress of the mental disease known as dementia precox, would be noted and chronicled, so that, if examined from period to period, his rate and amount of deterioration would be ascertained. Or, as the study of this disease by scientists and doctors results in an understanding of its causes, and in methods of checking its progress, the young man might, at a fairly early stage, be saved the later course of the development of the disease. This class of mentally disabled, alone, presents tremendous difficulties to any social organization and de-

mands consideration of new ways to be worked with and cared for.

The defective delinquents, not intellectually backward, but morally incapable of keeping themselves out of trouble, or too weak in will power to be made responsible for their own deeds, would be found and classed together as a group to be studied and to be cared for by non-penal public institutions,—institutions which should be adapted to take advantage of the economic value of these delinquents.

The problem of syphilis in the community and its relation to mental disorders would be faced more frankly by medical and social agencies. Some persons do not agree with the policy of the Psychopathic Hospital in requiring the routine Wassermann test, but the importance of the problem and its relation to mental disease demands it. Dr. Southard has said on this subject: "We have. . . an important mission with respect to syphilis. When the patients admitted to a state institution for the insane show positive Wassermann reactions in 22% (H. L. Paine's data, Danvers State Hospital) or, as at times for certain months at the Psychopathic Hospital, from 25 to 28%, it is high time that social workers and economists, as well as physicians, should begin to take an interest in that field of mental hygiene which shall seek coöperation with the sex hygiene propagandists."<sup>14</sup>

That the treatment and study of syphilis is legitimately a state issue is being more and more generally conceded. The appropriation of \$4000 by the Massachusetts State Legislature (April, 1914) to be spent for Wassermann tests by the State Board of Health, is but an indication of the fact that the disease is here recognized as a public menace, to be dealt with by public measure. More data showing the relation between syphilis and mental disorders, would be of great value in a propaganda for the state control of the study, treatment and prevention of the disease.<sup>15</sup>

Routine mental and psychological examinations would, therefore, throw into the limelight of social welfare work the problems of the feeble-minded, the early dementia precox type, the defective delinquent, sufferers from latent syphilis, and the other so-called asocial groups, each so largely represented in mental disorders, and requiring unlimited thought, care, trouble and expense on the part of private and public organizations and institutions. After all, it is the community which bears the brunt of the now unscientific method of dealing with these problems. The income from high rates of taxation now contributes far more to the care of the diseased, delinquent and defective members of the community than to the prevention of the causes of these unfortunates.

A systematic investigation of the mental condition of the chronic dependent, the delinquent, and the asocial members of the community would lead from the more general campaign for social

welfare to a broader and yet more definite campaign for mental welfare. It should in time save money to the taxpayer.

## PART II.

### A SURVEY OF CERTAIN SOCIAL ORGANIZATIONS IN BOSTON SHOWING THE RESULTS OF THEIR USE OF MENTAL TESTS.

To what extent the intensive study of the mental development of an individual should or could be carried by an organization is a much discussed question, and one which calls forth decided differences of opinion.

It was with a desire to gather these opinions, and to determine as far as possible the extent to which organizations working with social problems were already interested in and active with the question, that the following study was undertaken. It was made from the reports of 27 social organizations of Boston and vicinity, and showed some interesting facts relative to the theme of this paper.

In order to secure the necessary data, a questionnaire was sent to seventy-five organizations, chosen at random. The questionnaire covered the work of one fiscal year previous to the summer of 1914. The organizations included social service departments of business houses, private and public child-caring agencies, family rehabilitation and relief agencies, homes for dependent women, settlements and churches, school visitors and nurses. Twenty-seven of these responded. Although this number is small, the 30,410 cases\* enrolled by these organizations, and from which this study was made, should make the figures fairly representative.

Those who did not respond to the questionnaire gave various reasons for their inability to do so. The business houses, as a rule, kept no physical or social records of their employees. This was also true of some churches and their parishioners. A few agencies had not given sufficient thought to their mental problems to note them on their records. Others, who kept careful histories of their cases and dealt with large numbers, were not able to pick out the ones representing psychopathic problems, because their system of recording did not make the year's work readily accessible. Still others had not the time to devote to a special study of this type because it required, in their particular instances, a handling of every record worked on during the year. Some few questioned the value of such a study in proportion to the time and effort demanded of them to secure the necessary data. Many in the groups mentioned also objected strongly to the giving of names, although each organization was assured that the names were wanted only to prevent duplication, and would be destroyed as soon as the reports had been checked with each other.

Several of the 27 agencies which did respond had difficulty in collecting data, and expressed a regret that they had not kept more accurate and more accessible references to their psychopathic problems.

In the spring of 1914, the following form was sent to each of the 75 organizations. The immediate object of the questionnaire was first to ascertain as far as possible the number of mental cases in each agency, and their proportion to the total number of individuals dealt with by each group; and, secondly, to obtain an estimate of the extent to which each agency felt it should have gone in having others under its care examined:

#### QUESTIONNAIRE.

1. What was the total number of individuals dealt with during your past fiscal year?
2. How many were diagnosed epileptic? (Give names.)\*
3. How many were diagnosed insane? (Give names.)
4. How many were diagnosed feeble-minded? (Give names.)
5. How many were examined and diagnosis given of "borderline or doubtful"?
6. Give estimated number of individuals for whom you felt an early examination would have been advisable, but was not given.

The following organizations reported:

1. Boston Associated Charities.
2. Boston Children's Aid Society.
3. Boston Children's Friend Society.
4. Boston Children's Institutions Department.
5. Boston Juvenile Court.
6. Boston Provident Association.
7. Brookline Friendly Society.
8. Cambridge Associated Charities.
9. Catholic Charitable Bureau.<sup>†</sup>
10. Church Home.
11. Filene & Company, Social Service.
12. Florence Crittenton Home.
13. Federated Jewish Charities.
14. House of Mercy.
15. Jamaica Plain Friendly Society.<sup>†</sup>
16. Llewellyn Lodge.
17. Paine Fund.
- 18 and 19. Public School Studies (two)
20. Salvation Army Rescue Home.
21. Society for the Care of Destitute Mothers and Infants.
22. Somerville Associated Charities.
23. South End House.
24. State Infirmary, Social Service.
25. State Minor Wards.
26. Temporary Home, Shawmut Avenue.
27. Waltham Watch Factory, Social Service.<sup>†</sup>

\* Names were not given where there was duplicate duplication, but there was very little overlapping of lists.

† Did not give names.

\* In the seven agencies which dealt largely with family groups, the family is counted as a single case.

That the organizations reporting on the questionnaire represented work of varying extent was indicated by two classifications, one showing the total number of individuals dealt with by each organization during the year, the other showing the type of work done.

Classified according to the numbers which each agency worked with, there were:—

2 organizations dealing with less than	100 cases
8 organizations dealing with from	100 to 250 "
5 " " " "	250 to 500 "
4 " " " "	500 to 1000 "
1 " " " "	1000 to 5000 "
1 organization " " "	6072 "

Nine of these organizations dealt chiefly with family groups, and from seven of them it was not possible to secure the total number of individuals included in the work done. As the reports showed only thirteen defective individuals in families already represented once, these thirteen were thrown out and the percentage of psychopathic individuals for each agency was made upon the basis of the number of cases.

The totals, therefore, showed 984 cases in which at least one individual was insane, epileptic, feeble-minded or borderline. Seventeen per cent. of these 984 persons were diagnosed insane, 10% were epileptic, 53% were feeble-minded and 20% were doubtful or borderline.

In the second classification of agencies there were:

	TOTAL
Family rehabilitation and relief agencies (private)	9
Child-caring agencies { Public 3 } .....	7
{ Private 4 }	
Homes for dependent women { Public 1 } .....	6

From the reports of these agencies, two percentages were made. The first showed the percentage of diagnosed epileptic, insane, feeble-minded and borderline cases (questions 2, 3, 4, 5) in the total number of cases dealt with; the second showed the percentage of such cases in the total number when, to the cases diagnosed, were added the estimate of those persons who, it was thought, should have been examined, but were not (question 6). The second table has no value statistically, except to indicate to a certain extent the feeling on the part of the agents in regard to the importance or value of the use of mental and psychological tests for the asocial persons or those not obviously considered in need of an examination. No effort has been made to use these figures except to report them in the following table, as given.

Judging from the fact that most of the figures were obtained by going rapidly over the records of the year's work, it is highly probable that none of the returns are as full as they would have been had a systematic list of the epileptic insane, feeble-minded, borderline or doubtful

cases been kept by each organization from day to day.

Arranged according to the increasing order of the first percentage made, the organizations gave the following figures. Where no change was made in the estimated number of mental cases, the agencies felt they had secured the examination for all persons who had needed it.

Considering the types of individuals under the care of these organizations, the foregoing figures seem to fall into four groups.

The first group brings together the employees of one factory and of one general department store, a portion of the population of one neighborhood house district and persons represented by studies from public schools in two economically poor sections of the city. Altogether, they may be considered a cross section of a community with which social agencies of all kinds are concerned. (See Table I.) The total percentage of psychopathic individuals reported in this group is .3% of the given population.

Total Mental Cases	7.9%	

This population represents a community made up of people who are working for generally small wages. On the whole, they are considered normal,—most of the distinctly abnormal individuals having been placed in institutions. And yet when we compare this .3% with the .5% which represents the total number of insane, epileptic and feeble-minded persons receiving institutional care in the total population for the state of Massachusetts, there is an astonishing similarity in point of average.

There are two possible explanations for this: first, the actual percentage of the mental cases receiving custodial care is probably far below what it should be. Dr. Fernald's report of the results of an intensive study of the feeble-minded in Massachusetts, which was made following the 1912 census of the State Board of Insanity, states that there are in the community at least five times as many feeble-minded persons needing custodial care as there are those now receiving it. There is also undoubtedly a large proportion of insane and epileptic persons in the community who ought to be given custodial care. As there has been no intensive study made of either the insane or the epileptic in this State, it is impossible to make any estimate which would correspond with Dr. Fernald's study of the feeble-minded.

The second comment is that the community cross section used in this study represents an economically low group of persons. Among them one finds many of the borderline boys and girls, and men and women who are not committable to institutions and are capable of earning the lower wages. In the two public school districts and the neighborhood house district the families represent the struggling masses. We

know that the industrial and professional life of our country is supported to a great extent by men and women coming from the lower economic classes of society, but it is also true that in this stratum there is a large proportion of persons who never rise above it.

Where one finds in this class no improvement from generation to generation, one is apt to find a low grade of mentality as well as physical, mental and moral disease in varying degrees. It might, therefore, be expected that here one would find a large number of the insane, epileptic, and feeble-minded. It is in this economic stratum that most of the cases known to the other twenty-two social agencies are found.<sup>18</sup> It seems fair, therefore, to compare the percentages of the three following groups with this chosen cross section of the community.

The first group for comparison is made up of agencies caring chiefly for families and undertaking family rehabilitation. It shows that 3% of the persons known to them have been diagnosed as psychopathic. The second group is made of agencies caring for dependent and delinquent children and has 4.5% of mental cases. The third group includes the Temporary Homes for Women and agencies dealing with unmarried mothers. Here there is a distinct rise found in their 7.9% of mental cases. (See Chart I.)

Returning to the detail of the last three groups, it will be seen that in the Family Rehabilitation and Relief Association the percentages range as follows:

	PSYCHOPATHIC
Somerville Associated Charities.....	1.1%
Bedford Home for Women.....	1.4
Provident Association.....	2.0
Federated Jewish Charities.....	3.1
Cambridge Associated Charities.....	3.0
Boston Associated Charities.....	3.8
Brookline Friendly.....	4.2
Jamaica Plain Friendly.....	7.3
Paine Fund.....	13.5

The sharp increase found in the 13.5% of the Paine Fund may be accounted for in part by the fact that a large percentage of the individuals aided by that fund are those who have passed middle age without having been able to provide the means of livelihood for the later years of their life. There are many aged persons who are dependent through no fault of their own, but they are entirely outside of the group of those whose histories show indigence and delinquencies. The Paine Fund cares largely for dependent single persons, and for married ones who are without relatives to help them. The secretary of the society has but a comparatively small number of applicants during the year, so that it is possible for her to work in close coöperation with the medical agencies and give her applicants very personal attention.

As a whole, the family group of organizations has a surprisingly low percentage of insane, epileptic and feeble-minded.

One is inclined to feel that families which must be aided and supervised from year to year and are unable to rise above the need of it within the course of two or three years—as a portion of them are not—must be, to a great extent, handicapped by a subnormal or diseased mind. It would be worth while with this group of family rehabilitation agencies, to make an intensive study of the 343 families in which this report finds diagnosed 343 psychopathic individuals. It is significant to note just here that from all of the figures sent in for this study, there were only 13 other mental patients reported as belonging to these 343 families. This would indicate that either the data were incorrectly recorded or that other members of families in which there are mental patients are not being recognized.

An intensive study of these 343 families should ascertain the number of years each has been under the care of a social agency, the kind and amount of aid given, and the results secured in proportion to the time and money spent after a stated number of years. It should also determine the number of other members in the family showing signs of disease or defect. This information is evidently important in studying the group of psychopathic persons already recognized. Is it not also important to look into the mental condition of the members of those other families which drift along from year to year, apparently content with gaining mere sustenance, getting out of difficulties, and ending

their days supported by some fund or by a private or state institution?

Both state and private institutions would contribute toward the improvement of the community at large, as well as to the efficiency of their own work, if it were possible at an early stage in the history of these families, to obtain their mental status.

It is not at all surprising that the total number of mental cases in this family rehabilitation group is 3% of the whole, as compared with the 3% mental cases of the cross section, representing the community in which most of them are found. On the other hand, if for one year these family rehabilitation agencies were to catalogue or signal every individual with mental disease or defect known to them during that time, and if they were to make a greater effort to have examined more of their eccentric applicants and those offering particularly difficult problems, it is quite probable that the total number of mental cases would increase in percentage. The present figures are of value only as a basis for comparison in a further study.

The child-caring group as here given includes the organizations responsible for delinquent children, as well as those caring for dependent children. This at first seemed to be a doubtfully fair grouping, but inquiry brought out the fact that most of the agencies caring for dependent children were attempting close coöperation with the Juvenile Court, and were boarding out and supervising many children for whom the court had advised a change of environment. Some children in the care of these agencies had also acquired court records, so that they were already classified among the delinquent. The problems, therefore, of the agencies dealing with the dependent and the delinquent children seemed closely enough related to warrant their being classified together in this study. Seven agencies reported their mental cases as follows (all duplicate names have been eliminated):

	MENTAL CASES
Catholic Charitable Bureau.....	1. %
Children's Institutions Dept.....	1.6
Boston Juvenile Court.....	2.3
Children's Friend Society.....	2.9
Children's Aid Society.....	3.4
State Minor Wards.....	5.9
Church Home.....	12.7

The total percentage of mental cases for this group is 4.5. Five of these agencies already attempt to have physical examinations for their children before any responsibility is assumed, but they are not given as routine. The State Minor Wards has its own physician, and has every child examined before accepted for its care. They had under supervision during the year reported on 6072 children, 361 of whom were feeble-minded, epileptic, insane or borderline. The State felt the need for the physical examination of these children, and the means for providing it was found. The psychological examination will be more uniformly used, and equip

ment for it will be provided, as agencies like the State Minor Wards feel the need for psychological as well as physical examinations.

In the work for children there are two reasons for establishing the mental status of each child. First, to detect the feeble-minded and subnormal; the value of this is obvious. The second is to be able to record a definite mental rating for the normal child in order that future mental tests, over periods of perhaps five years, may show whether the patient is developing normally, or is deteriorating. Most of the dependent children have a poor heredity, and even though unusually bright in childhood, may, during adolescence, show arrested development or a beginning psychosis.

In order to make a diagnosis of a beginning psychosis in a child, it is important to know whether or not he has deteriorated, and if so, at what age the deterioration appeared, and along what lines. With the inevitable frequent changing of supervising agents, this information cannot be obtained accurately from social records. The routine use of standardized psychological tests offers the only scientific method for acquiring this part of the history of a child.

The 4.5% representing the total percentage of mental cases reported by these child-caring agencies shows an increase over the 3% mental cases reported by the family rehabilitation agencies. This does not at all signify that there is a larger amount of mental disease and defect found in groups of children than in the social groups, including children and adults. It is rather more probable that the child-caring agencies have been able to secure an examination for a larger proportion of their cases than the family rehabilitation agencies have secured. It is quite natural that this should be so, since the children's agencies have far greater control over the children under their care than any of the family rehabilitation or relief agencies have over their applicants. In comparison with the .3% mental cases in the community cross section, it is, however, important to note that so large a percentage as 4.5 defective and mentally diseased children should be found among these special children's agencies.

An analysis of the percentages of the seven agencies calls forth further comment. The first six percentages range from 1% to 5.9% mental cases, while their total percentage is 2.8. On the other hand, the Church Home, which is the seventh agency in the group, stands by itself with 12.7% mental cases, in spite of its endeavor to raise its standard for the type of child taken under its care. It is probably significant that during five months of the year reported on, the Church Home secured a mental and physical examination for every new child accepted for care of any kind. This would seem to indicate that we are not in a position to estimate the number of defective and insane children without a more

extensive use of psychological and physical examinations.

The last group of agencies, and perhaps the one most urgently in need of a systematically intensive study of mental conditions, includes those agencies helping stranded women of various types. Conspicuous among these women are the many unmarried mothers. Some of the child-caring agencies are making an effort to supervise, outside of institutions, certain of these mothers, but the temporary homes still are necessary for some purposes. Unfortunately, we have not been able to secure figures from those child-caring agencies which have recently undertaken the boarding-out phase of this work. The following reports are from temporary homes (with one exception). Arranged according to the percentage of women diagnosed psychopathic, the reports show:

#### MENTAL CASES

Florence Crittenton Home .....	2.2%
Salvation Army Rescue Home.....	2.5
Temporary Home for Working Women .....	2.7
Destitute Mothers and Infants.....	7.0
House of Mercy.....	17.9
State Infirmary, Social Service.....	23.0

The total per cent. is 7.9, but a closer analysis is important. The first three institutions have a striking similarity in the number of mental cases they have detected, the number being indicated by 2.5% of the total number of persons worked with. In each of these homes the supervisor is interested in the girls under her care, and is anxious to secure an examination for those who are not thought to be normal. On the other hand, the Society for Helping Destitute Mothers and Infants, which places many unmarried mothers at work and in boarding homes, and bases its treatment upon investigation and observation, shows an increase of over 4% of psychopathic women. It is hardly possible that this agency has under its care a lower type of woman than that which usually seeks shelter in an institution. But a still more striking rise in percentage is found in the average of the two institutions dealing almost entirely with unmarried mothers, namely, the House of Mercy and the State Infirmary (Social Service), both of which have endeavored to make a systematic study of the mental condition of those in their care, no matter what the circumstances of the mother's life may have been. The 22.3% average of these two institutions would indicate surprising returns from the systematic use of mental tests.

The foregoing are the figures, however, for the unmarried mothers, who are, for various reasons, dependent but not necessarily delinquent, to any great extent. It is, however, interesting at this point, to note from the Massachusetts Commission for the Investigation of the White Slave Traffic in 1911, that in a series of 100 women prisoners, 13500 from prisons, another 100 from detention homes, and a third

MENTAL CASES FOUND IN AGENCIES DEALING WITH ILEGITIMACY. Classified according to the extent to which mental tests were used.

Results of a study of 300 prostitutes by the White Slave Commission.

CHART II.

from industrial schools, 51% of them were found to be feeble-minded and 3% were insane, making a total of 54% psychopathic. (See Chart II.)

That there should be 7.9% total mental cases found in these Temporary Homes for Women is not at all surprising; rather, one might expect to find a much higher percentage of the defective or mentally diseased in a group in which the unmarried mother forms so large a part. One does not condemn all unfortunate women as necessarily insane or feeble-minded, but figures are pointing out more and more clearly that mothers with illegitimate children who become dependent or are brought before the courts, include enough feeble-minded and insane among them to make further systematic inquiry important.

In conjunction with the study of these four groups, it is interesting to analyze the figures in such a way as will show comparative relations depending upon the different technic employed by the four groups of agencies.

With respect to their manner of selecting patients for examination, these twenty-seven organizations fall into three classes, namely: (1) those who have persons examined only when the disease is obvious; (2) those who base the need for an examination upon a suggestive history including heredity, conduct and general physical symptoms, in part or all together; and (3) those who believe in a routine mental examination for every individual under their care, but for various reasons have been able to secure it for but a given portion. This last class of agencies may be designated as those who have systematically used the mental tests.

CHART III.

A STUDY IN TECHNIC. THREE GROUPS IN THE STUDY OF TWENTY-SEVEN SOCIAL AGENCIES.

The extent of their use of mental tests and the respective results as represented by the percentage of mental cases found in each group.

There were thirteen of these agencies who made use of special examinations only when the defect was obvious. (See Chart III.) Their total per cent. of psychopathic cases was 1.3%. There were eleven agencies who based their use of special examination upon any history of their charges which suggested the need for examination, and their total mental cases amounted to 4.3% of their whole number dealt with. There were just three agencies attempting to make a systematic inquiry into the mental status of their charges, and the result of this effort showed 19.2% of their charges to be psychopathic. Two of these three agencies dealt with unmarried mothers, and one cared for dependent children.

Applying this same method of classification to the Temporary Home group, which is characterized so largely by its problem of illegitimacy, and comparing the total percentages of its three classes with those of the same three classes for the whole twenty-seven agencies as given above, we have what appears to be a closely corresponding increase in percentages, depending upon the method of selecting patients for examination. (See Chart IV.) In the Temporary Home group, examining for obvious defect, the percentage of mental cases is 2.5% as compared with the 1.3% for this class in the whole group. The Temporary Home group has 7% mental cases in the agency basing its use of special examinations upon the suggestive history of the patient, as compared with 4.3% mental cases for the whole group of agencies. Again, the Temporary Home has 22.3% mental cases in the agencies making a systematic use of the mental tests as compared with 19.2% mental cases in the corresponding class for all the agencies.

A COMPARISON OF I AND II, BASED ON THE USE OF MENTAL TESTS.

TWENTY-SEVEN SOCIAL AGENCIES STUDIED

CHART IV.

Just how significant this analogy is can be determined only by a further study of these agencies and the results of their uses of mental tests.

### PART III.

#### CONCERNING THE USE OF ROUTINE PSYCHOLOGICAL EXAMINATIONS FOR CERTAIN AGENCIES.

We have not yet come to the era when all persons shall be ranked by society upon an efficiency basis,—when the stagnant men and women, the non-producers, whether rich or poor, shall be looked upon as one and the same, socially as well as economically, or when the ability of men and women shall be gauged by methods which will approach a uniform standard. The day may come, but until that time the public is particularly concerned with the mental status of those members of the community who, because of mental, moral or physical weakness, or because they are unable financially to care for themselves, are costing the State and private organizations large sums of money and much thought and work.

For the public and private agencies dealing with dependency, delinquency, child-caring and illegitimacy problems, the use of a routine mental and psychological examination, combined with the physical examination and Wassermann test for syphilis, seems to be the most direct means of finding the primary causes of their problems.

Directors, physicians and psychologists in psychopathic hospitals and psychological clinics are persistently considering and testing practical and fair methods for rating the mental status of the patient. It is their endeavor to make the application of the tests advantageous to the work of the various organizations employing the clinic, quite as much as that they

should have the results of the tests as a basis for study and improvement.

In order to get the opinion of the representatives of social agencies in regard to the possible benefit to be derived from a routine use of mental tests, a second letter was sent to each of the twenty-seven agencies which responded to the first questionnaire. Opinions were expressed in favor of and against such a system. A few of their replies are quoted in part.

Some of the child-caring agencies wrote as follows: "Children in our care are under such close supervision that when the need for mental examination exists the visitor is prompt to discover it, and the examination may then take place." Another wrote: "Such an examination would give rise to serious objection on the part of the public at large, especially the parents and guardians of the children."

Still another said: "For patients who have indicated no mental instability in their past lives, the examination produces a state of mind which very much affects the social treatment. This applies to children, as well as to unmarried mothers."

One agency, which has been urging a central medical examining agency to which all might send their children, says, "The more I consider the administrative side of such a central agency, the more do I sense the dangers there are in having the personality of the individual more or less lost in a large group of others who are being examined. Under the present methods of examination of children, I have felt that the conditions were neither normal nor fair to them. I wish it were possible to have all the patients meet the physicians in so informal a way as not to give them the slightest indication of what was being done."

Another agency, dealing with 100 children in a year, thought the problem would be too big for the present psychological clinics, and to employ its own alienist would be too expensive. It suggested that, as a matter of economy and practical social administration, we should have to be content at present with eliminating from these examinations all children who are practically up to grade in school, and have not shown themselves to be unusually troublesome or obviously peculiar.

One of the agencies which has advocated and tried a systematic use of mental and psychological tests, writes that: "A routine mental and psychological examination is of great value in connection with the various problems of child-caring and allied subjects, provided it is done from the point of view of the society and with a social outlook. Such an examination, to be valuable to us, must have a practical significance, and must be done with the same social point of view that we require in a physical examination. To be helpful in placing the results of the examination must be obtainable within a short time of the examination, and

should include definite recommendations as to ideal surroundings, just as, again, the good physical examination carries with it recommendations as to hygiene, etc."

From those agencies caring for unmarried mothers one wrote: "Such an examination would be both helpful and interesting, but not possible under our present administration because of lack of time and workers." Another believed that in all cases where there was any question of doubt about the mental condition of the mother, or where her future disposition presents some difficult problem, the examination would be of great assistance; in others it would be an unnecessary ordeal. A third wrote: "So far as our work with unmarried mothers is concerned, I believe that mental and psychological examinations should be made in every case."

From the family rehabilitation and relief agencies there were more dubious opinions. One wrote: "So far as including a routine mental examination for all dependent families and the out-door poor, I am not so certain. Many should undoubtedly be examined. Whether all or not, I should want to think longer before answering. Of course, our charges, from the children to the aged, offer rich material for psychopathic study. Present facilities make it impossible to identify all of the mentally disordered cases which we handle."

Another mentioned the difficulty in having a family which appeared perfectly normal in every respect, submit to an examination, and felt it would be embarrassing to have all families examined.

One other felt that privately supported family rehabilitation agencies could not take advantage of the use of mental tests generally until the public, which supported the agencies, demanded its use.

A critic in close touch with the family rehabilitation agencies said: "I find myself wondering whether the very compactness and air of finality that belongs to a mathematical rating should not make us more cautious in recommending its use for all, or nearly all, clients of social agencies."

"A possible and safer next step on the long road that we have to travel would be the instruction of educators and social workers in the signs embedded in personal and family history and in the symptoms presented by the individual himself, which would indicate the possible need of a mental examination."

From these comments it is evident that the practical need for a better appreciation of the mental status of social clients is already felt to a limited extent. It is undoubtedly but a matter of time, and the education of public opinion before the use of psychological and mental examinations will be established as a necessity in the program of every social agency undertaking the supervision of delinquents, dependent chil-

dren, chronically dependent adults and women with illegitimate children.

Stated briefly, the most important objections to the routine use of mental tests are as follows:

1. There is too great difficulty in securing the mental, as well as the physical, examination of large numbers of social patients. This objection is resolved into three parts: (a) Where agencies do not have their own psychiatrist there is the difficulty of getting adult patients to go voluntarily to a clinic which suggests possibility of mental trouble in patient. (b) The clinics at present are not equipped to handle large numbers. (c) The public does not yet appreciate the value of such a proceeding.

2. Many social workers feel there is danger in relying too greatly upon the results of the psychological tests, which in their minds are not far past the experimental stage.

3. The expense of maintaining a psychiatrist or psychologist is too great for the average social agency, and there is danger of lowering the general standard of psychiatric work where individual psychiatrists are employed.

4. Social workers should have more knowledge of psychopathic symptoms and problems in order to make proper use of the results of such examinations.

5. The other objections fall under the head of criticisms of administration.

The first objection is found most evident among the family rehabilitation and relief agencies dealing with the chronically dependent adult. In these agencies it is true that the applicants are largely referred by privately philanthropic persons, and an effort to get these applicants voluntarily to a psychopathic hospital is usually fruitless. It is here also that the public, among whom are these privately philanthropic persons who referred the applicants, will be most quickly aroused to harsh criticism of the agencies' methods. Their untrained sympathies so often resent any appearance of red tape. If, however, the public could see the importance of knowing the applicant's mental status, a satisfactory technic would undoubtedly be worked out. For example, all family rehabilitation and relief agencies must always do a certain amount of emergency or temporary work in order to prevent the possibility of suffering, and acute problems would not, therefore, be hampered by routine. But where constructive work for families or individuals is undertaken, and financial assistance is offered to cover a protracted period of time, a routine system of examination would facilitate treatment greatly, not only because of its assistance to the social worker in making a well grounded plan, but also because the applicant would not be inclined to resist an examination which would be required of all under similar circumstances. The sting of being singled out as "peculiar" would be removed. One research worker has suggested that a beginning be made by securing systematically a physical

and mental, or psychological, examination for the members of any family which has not been able to establish its social independence within two years. The time element, of course, would not be significant with those families for whom an adequate pension and supervision over several years has been planned by an agency,—in such families, for example, as those of widows, of certain deserted wives, and those in which the breadwinner suffers from an incurable disease. But with these latter families, as previously suggested, one should have a knowledge of the mental and physical condition before determining the plan for their future.

With the children's agencies, the difficulty in securing mental tests lies chiefly in the proper handling of large numbers. The State Minor Wards, for example, had 6072 children under their care during the year reported on. If this agency had begun with the 850 children, whom they received during that year, there would not have been more than three patients a day to be examined. A complete psychological examination, including the Point Scale, the Binet and Healy tests, seldom takes over two and a half hours.

The agencies dealing with unmarried mothers would also obviate their great difficulty in getting the patient to the clinic if the tests were given as routine.

That the clinics are not yet prepared to examine as many patients as such general use of mental tests would necessitate, may be true, but the inevitable law of supply and demand would regulate this. Not only would the present clinics be better equipped, but new clinics would be opened.

The second objection—the danger of relying too greatly upon the ratings of the psychological tests and the distrust expressed as to the practical value of these tests in their present stage of development—is one that is often heard from social workers. It is, however, ungrounded except where unwarranted claims have been made for the tests. When used by skilled psychologists, the results of the examination have definite values, and lend themselves to practical interpretations. The special worth of each method of examining should be known, and it is usually advisable to combine two or three different methods of testing in order to check the results.

The third objection—the expense involved—should an agency employ its own psychiatrist and develop an independent small clinic of its own—is one which can be met only by the education of the public which supports these agencies. Four of these twenty-seven organizations already have an examining physician in their employ, and for them it would be necessary only to add a psychologist, and the usual psychological equipment. Both the physician and the psychologist should have had experience in a psychopathic hospital or a psychological clinic.

Social histories are already obtained and required by most social agencies, and if, in addition to the physical and mental examinations, arrangements were made for the taking of the Wassermann test on every case possible, the individual clinic would meet the needs of the average applicant, and could decide which individuals should be sent to a psychopathic hospital for observation and more thorough study.

By eliminating the less difficult cases of these agencies in this way, the demand upon the hospitals would be diminished. With such a system, agencies which assume the care of children or individuals over a period of years would have the means of making careful records of the mental improvement or deterioration of those under their care during the time known to them. An examination should be given at intervals of at least three years, but if the individual is supervised for less time, the examination should be given at least upon his admission and discharge.

The work of giving mental and psychological examinations should not be entrusted to social or eugenic workers, unless they have had, as a background, special training as physician or psychologist. The mere formality of subjecting a patient to a Binet or other mental examination will not meet the need which this paper has attempted to point out. Physicians and psychologists employed by social agencies as independent examiners should endeavor to standardize their work by securing as nearly uniform data as possible, and should have some means of interchange and discussion of methods and results.

The fourth difficulty, found in the lack of knowledge of psychopathic problems on the part of the social workers, is one that is generally felt. It is not only acknowledged by social workers, in their inability satisfactorily to select patients for examination, but also in the difficulty which they find in dealing with the non-committable psychopath. That social service departments of psychopathic clinics should undertake to supervise all of these non-committable cases, especially where another agency has already established friendly relations, is impractical. But that social workers in training should have certain courses on psychopathic problems and a required amount of practical experience in a psychopathic hospital or clinic, is undoubtedly the final solution of the difficulty.

Objections to the administration of the clinic such as complaints made of the manner of approaching the subject of examination to a patient, etc., may be based on exceptional instances. Mistakes would be corrected, if reported to the proper authority.

Aside from the special study of their charges from the mental point of view, social agencies should develop a system of indexing their psychopathic patients so that, whether using rou-

tine examination or not, these patients could be readily referred to. Certain social organizations find it expedient to keep an index of the community problems which appear from day to day in their case work.<sup>17</sup> For example, those families under their care in which there is found disability from industrial accident are indexed in a section so named. Other index headings include child labor under fourteen, dependent widows, blindness, illegitimacy, and various problems of current interest. In such an index there should be introduced a section for the insane, the feeble-minded and the epileptic, and a fourth one entitled, "Other types of nervous instability." This fourth group of nervous patients would include those social patients commonly referred to as "queer" and "particularly troublesome and difficult to work with" as well as those whose social history suggested mental disorder or defect, but whose examination resulted in a diagnosis of "not insane" or "not feeble-minded" at the particular time stated.

The social organizations making use of such an index have found a particularly effective use for it in their publicity work and in the preparation of special leaflets and pamphlet studies, preparation of annual reports, legislative campaigns, provision of data for commissions and social investigations, as well as for the intelligent supervision of their own work.

The agencies which will so index their mental patients will be ready with valuable material for the propagandists and students of mental diseases. They will also be taking a first step toward the establishment of a larger institution, namely, state registration of all insane, feeble-minded and epileptic.

Without a systematic study of their charges, with an eye to identifying those with mental disorders, the organizations giving relief, readjusting home and industrial conditions, promoting prophylactic measure, or caring for the welfare of the child, cannot estimate the part which the psychopathic patients play in their respective problems. Whether or not a patient is committable to an institution is not the all-important question for the community. How to deal with those patients who are not committable—most of whom must return to their former friends and helpers—should interest each organization even more than the weeding out of the committable ones.

#### RECOMMENDATIONS.

1. A way should be provided by which all social workers in training should be given instruction in the social and general signs of mental diseases. This instruction should include experience in work with psychopathic patients.

2. Social organizations of every type should keep an index, either by signal or card catalogue, of the insane, epileptic, feeble-minded and distinctly asocial persons enrolled.

3. There should be developed a central bureau of registration for persons included in the above four types.

4. All agencies dealing with unmarried mothers, delinquents and dependent children, should establish as an essential routine a careful physical and mental examination of every individual under their care.

5. Agencies dealing with dependents who are not delinquents should establish as part of their necessary routine a system by which families or individuals dependent for more than two years, or families for whom an agency is planning to give considerable aid and supervision, shall be given a thorough physical and mental examination as early in the treatment as possible.

6. All children in the care of social agencies, whether normal or borderline, should be given mental examination upon admission and discharge, and if supervised for several years should be examined at intervals of from three to five years.

7. The existing psychiatric clinics and psychopathic hospitals should be enlarged and equipped to meet the increasing demands made upon them.

8. When these centers can no longer care for the patients, other psychological clinics and psychopathic hospitals should be supplied.

9. Should social agencies prefer to employ their own psychologists or alienists, these specialists should work together in such a way that their work would be standardized and the data be as nearly uniform as possible.

10. All psychological or mental examinations should include the Wassermann test for syphilis, as well as a physical examination and social history.

## Clinical Department.

### MULTIPLE PRIMARY HETEROGENEOUS TUMORS: A CASE OF TWO PRIMARY MALIGNANT TUMORS, ONE OF THE KIDNEY, THE OTHER OF THE STOMACH, WITH METASTASES FROM EACH IN THE LIVER.

By STUART GRAVES, M.D., LOUISVILLE.

[From the Pathological Laboratory of the Boston City Hospital.]

An autopsy which revealed a typical hypernephroma or adrenal cell carcinoma of the left kidney and a typical adenocarcinoma of the stomach, each with metastases in the liver, prompted a study of the subject of multiple primary tumors and a review of the literature on that subject. There are many articles, a perusal of which brings out the following facts: (1) multiple benign primary tumors, especially homogeneous neoplasms, such as leiomyomata, lipomata, etc., are common; (2) combinations of malignant and benign growths of different cell origin, such as carcinoma of the mammary gland and leiomyoma of the uterus, are not uncommon; (3) multiple primary malignant growths of homogeneous nature, such as bilateral carcinoma of the mammary glands or bilateral hypernephroma of both kidneys, are less common than (2); (4) multiple primary, malignant, heterogeneous tumors, such as in the case herein reported, are extremely rare. The last class might be subdivided into two; (a) epiblastic (carcinomatous) growths affecting different systems with different forms of new growth, such as carcinoma of mammary gland and carcinoma of colon, and (b) multiple primary, malignant growths of different embryonic cell origin, such as epithelioblastic and fibroblastic. Of the two subdivisions, the second is probably the rarest of all.

In the laboratory of the Boston City Hospital no case of multiple primary, malignant, heterogeneous tumors beside the one submitted in this report, has been found in 4586 autopsies. Three other cases have shown multiple primary, heterogeneous tumors. For example, one case (04.41), female, death from bronchopneumonia, showed adenoma of left adrenal gland, leiomyoma of uterus, fibroma of ovary, rapidly growing leiomyoma of broad ligament, adenomas of liver and so-called cavernomas of liver. Another case (05.150), male, 51, death from rupture of esophageal vein, secondary to cirrhosis of liver, showed carcinoma of colon, papillary adrenal tumor of kidney with adenoma of kidney. A third (16.71) showed carcinoma of the pancreas with metastases into the retroperitoneal lymph nodes, intestines and bladder wall; also papillary adenoma of the right kidney about 5 cm. in diameter, apparently benign. It is seen that none of these cases showed clean-cut malignancy with metastases of tumors of a different cell type arising in different systems. In examining the reports of similar cases the same fact is striking,—that multiple, primary tumors of proved malignancy, either of the same embryonic cell type in different systems, or of different embryonic cell types, are extremely rare. This case to be reported is also unusually interesting in showing direct extension of the tumor along the venous system. The record is in part as follows:

C. F. H. Male, white, 64 years old. The emaciated condition and slight yellow tinge of the whole body is striking. Superficial veins are everywhere dilated, standing out prominently on the abdomen. Lower ribs are everted. Just below the xiphoid there is a moderate bulging 6 cm. in diameter.

*Peritoneal Cavity.* In the upper left quadrant is a retroperitoneal mass over which lie dilated veins and the beginning of the descending colon. The bulging seen externally below the xiphoid is due to a tumor mass in the liver. The lymph nodes in the omentum and mesentery are slightly enlarged, largest 15 mm. in diameter, firm and on section pale grey and granular.

*Lungs.* In the left lower lobe is found a tumor nodular 1 cm. in diameter, firm, grey and granular.

*Gastrointestinal Tract.* The portion of the stomach which lies against the under surface of the left lobe of the liver on opening shows an irregular, cauliflower-like, thickened area 6 x 7 cm., which begins 2 cm. from the cardiac opening and measures from 5 to 13 mm. in thickness. Cut surface of this is hard and grey and the mucous surface shows ulcerating patches. Its color varies from pale to rosyish grey and dark red. A scarlet through this area into the liver shows a clearly cut differentiation along the peritoneal surface of the stomach for the most part, but in one place where the tumor is located the ulceration extends with tumor mass into the liver 25 mm.

*Pancreas.* The pancreas is diffusely affected in its proximal portion with the tumor nodules described above.

*Uterus.* White, 18 x 10 x 10 cm. (with dilated gall bladder and small portion of stomach attached).

HYPERNEPHROMA METASTATIC IN LIVER. X200.

ADENOCARCINOMA METASTATIC IN LIVER. X200

Organ presents multiple nodular masses, the largest of which is about 10 cm. in diameter. On section this shows a cleanly circumscribed tumor, about the periphery of which is a grey line. The tumor is soft and almost spongy. The cut surface varies from pale grey, most marked about the periphery, to dark red through the greater central portion. About the tumor mass liver cells seem compressed and the cut surface of the liver tissue is speckled with fine brown dots. Cut surface of tumor bleeds freely. There are numerous other tumor masses, some of which are not more than 5 mm. in diameter. Some of them appear to be blood vessels filled with tumor tissue.

**Kidneys.** Weight, right, 125 gms. It is small, firm and pale. The capsule is adherent and leaves a finely granular surface when pulled away, in which are a few small cysts. The cut surface shows indistinct markings, but the Malpighian bodies are visible as fine grey dots. Cortex, 10 mm. Cut surface is pale.

Left kidney is replaced entirely by a tumor mass 11 x 12 x 21 cm. Weight, 1910 gms. It is roughly of kidney shape. Its color is pale grey and yellow with red areas. The mass is extremely boggy. On section the cut surface varies in color from ochre to deep reddish brown, and is separated into large lobules by coarse strands of pale grey, depressed tissue. From the darker portions blood runs freely. The tumor tissue in places is coarsely granular and extremely friable. In the yellower portions there are mixed in places, indistinct, interlacing, irregular areas of pale, opaque, firm, colorless tissue.

**Adrenals.** The left adrenal is found on one side near the upper pole and, while closely attached to the tumor mass, shows nothing remarkable in itself. Right adrenal not remarkable.

**Note:**—The remarkable feature of the gross picture is the distention of the left renal vein and inferior vena cava with what appears to be tumor tissue consisting of a spongy, dark red and grey mass sharply defined by the vessel walls. Each vessel seems filled with its mass.

#### MICROSCOPIC EXAMINATION.

**Tumor of Left Kidney.** Sections show a very cellular new growth with very little stroma and many

capillaries, scattered through which are more or less extensive areas of necrosis and hemorrhage. The type cell is irregularly polygonal for the most part, but some cells tend to be round or polymorphous, or, in more cellular areas, spindle shaped. These cells vary greatly in size, some being very large. The nucleus of the tumor cells is round or oval, pale, vesicular, usually centrally placed, and has one or two distinct nucleoli. Some nuclei are hyaline. The cell membrane is distinct and the cytoplasm is scanty, faint pink and finely granular, the combination giving the tumor a reticular appearance. Some multinucleated cells are seen but no mitoses. Many tumor cells are filled with fine vacuoles, which correspond to fine fat globules in Scharlach R. stain. Other tumor cells contain dark greenish brown granular pigment, in small masses in the larger cells and filling the smaller cells. This pigment is seen more where the tumor is more cellular and less differentiated. The cells resemble adrenal cells. Although the stroma is fine and scarce, there are some broad, fibrous bands which are infiltrated with lymphocytes. The capillaries have very thin walls. In many places the tumor cells are arranged about cavities in which disintegrating tumor cells and many endothelial leucocytes filled with fine vacuoles are scattered through serum and erythrocytes. Some cavities contain masses of necrotic cells; others, serum only or red blood corpuscles only. There are also extensive areas of hemorrhage with scattered endothelial leucocytes containing greenish pigment granules. One kidney tubule seen. Microscopic diagnosis: adrenal cell carcinoma (hypernephroma).

**Lungs.** Section from base of left lung shows a circular area of tumor similar to the tumor of the left kidney, but with more stroma, growing expansively and compressing the alveoli of the lung about it. Microscopic diagnosis: metastatic hypernephroma.

**Stomach.** One section shows a spot in the mucosa where the epithelium is atypically arranged, tending to form small masses or glands with one layer of epithelium. Both cytoplasm and nuclei of these cells stain more deeply than in the corresponding cells of the neighboring mucosa. Numerous mitoses seen. Some of the masses are dilated into small cavities, some of which contain mucoid material. These glands and small masses of epithe-

lial cells at one point infiltrate the muscularis and muscle coat. Both normal mucosa and tumor are infiltrated with polymorphonuclear leucocytes, for which many tumor cells are phagocytic. Microscopic diagnosis: adenocarcinoma.

**Stomach and Liver.** One section shows the adenocarcinoma extending directly from the stomach into the liver, compressing liver cells before it. In the stomach wall some cords of epithelium lie in lymph spaces and fewer masses of epithelial cells in lymph vessels. The cells in the edge of the compressed liver are more or less degenerated and infiltrated with leucocytes, among which polymorphonuclear and endothelial leucocytes predominate. In the cytoplasm of a few are fine red, crystalline particles. In the stroma are many lymphocytes and endothelial leucocytes, containing pigment resembling hemosiderin. The more normal liver beyond shows congestion and some lymphocytic infiltration of the connective tissue. The surface of the tumor shows extensive areas of necrosis with masses of coeci, bacilli and thread-like organisms. Around the necrosis and infiltration of the tumor are many endothelial leucocytes, some phagocytic. Some of the tumor cells are phagocytic for leucocytes. Microscopic diagnosis: adenocarcinoma of stomach extending directly into liver.

**Liver and Inferior Vena Cava.** Sections show tumor similar to that of the left kidney, separated from the liver by a wall of vein to which it is attached along the greater portion of the line of contact. There are intervals along this line where spaces lined with endothelium contain erythrocytes, as if the lumen of the vein were not entirely occluded by tumor.

**Liver.** Various sections show tumor of both types described. In one section a growth of adrenal cell type is entirely surrounded by liver tissue. Microscopic diagnosis: metastatic carcinoma of both types described.

**Left Adrenal.** Section shows the greater portion of one half occupied with tumor mass resembling that of the left kidney. The tumor is surrounded by a narrow rim of cortical adrenal cells except at one point, where only the capsule intervenes between it and similar circumscribed tumor masses outside. One smaller, similar new growth is seen in either end. Part of the capsule is infiltrated with lymphocytes and contains a considerable number of cells with yellowish brown pigment. Microscopic diagnosis: metastatic carcinoma of adrenal cell type.

**Mesenteric Node.** Lymph spaces invaded with masses of epithelial cells with deeply staining nuclei and basic staining cytoplasm; mitoses frequent. Some masses inclose polymorphonuclear leucocytes. Many masses show necrosis, some having only stroma left. Microscopic diagnosis: metastatic adenocarcinoma.

#### FINAL DIAGNOSES.

Hypernephroma (adrenal cell carcinoma) of left kidney with metastasis in liver; adenocarcinoma of stomach with metastasis in liver and mesenteric node; hypernephroma of left adrenal; hypernephroma in inferior vena cava; bronchopneumonia; healed nephritis of right kidney; sclerosis of aortic valve, coronaries and aorta; edema and atrophic fat in epicardium; fibrous pleural adhesions; chronic splenitis and perisplenitis; atrophied testis; organized thrombi of iliac veins and sper-

matic plexus; dilated superficial abdominal veins; emaciation and malnutrition.

In conclusion I wish to acknowledge gratitude to Professor F. B. Mallory for the opportunity to report this case and for his helpful suggestions. The photomicrographs were made by Mr. L. S. Brown, of the Massachusetts General Hospital laboratory.

### Book Reviews.

*Surgery in War.* By ALFRED J. HULL, F.R.C.S. Major, R.A.M.C.; Surgeon, British Expeditionary Force, France; Late Lecturer on Surgical Pathology, Royal Army Medical College, Millbank; and Surgeon, Queen Alexandra Military Hospital. With a Preface by Sir ALFRED KEOGH, K.C.B., M.D. 390 pages, 26 plates and 55 text-figures. Philadelphia: P. Blakiston's Son and Company.

"Surgery in War" is the work of six or seven men who thoroughly understand the problems with which the book deals. They have succeeded in putting into one small, well-printed and readable volume exactly the things which a civil surgeon would wish to know in case he were called upon to serve in the army.

Only the strictly surgical aspect of military medicine is treated; such questions as those of sanitation and hygiene are untouched. The writers assume a knowledge of surgery on the part of the reader, and have omitted the mass of already well-known facts which tend to destroy one's interest in a treatise of this kind.

In a few minor points the writers show unfamiliarity with the latest advances. For example, they dismiss the subject of blood transfusion with the statement that the artery to vein method is the only safe method, and of course is seldom practicable under military conditions. They describe very clearly the best methods of treating septic wounds, chiefly the hypochlorous acid method of Carrel, and the hypertonic salt treatment of Wright and Gray. In their experience, the latter has been more efficacious.

Other chapters deal with the localization of foreign bodies; compound fractures; gangrene; hemorrhage; gunshot wounds of the head; injuries of the spine; wounds of the abdomen and of the chest; wounds of peripheral nerves. All are characterized by a practical, definite, common-sense attitude which makes the book a valuable guide to those who expect ever to practise war surgery, and interesting reading for those who would know something of the problems encountered therein. Many of their points are illustrated by well-chosen case-histories and by radiographs.

## THE BOSTON Medical and Surgical Journal

Established in 1812

An independently owned Journal of Medicine and Surgery published weekly under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, DECEMBER 28, 1916

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, \$6.56 per year for all foreign countries, by *mailing to the Postal Union*.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to:

ERNEST GREGORY, *Manager*,

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts

## PHYSICIANS AND THE INCOME TAX.

On January 1, 1917, Massachusetts embarks on a new method of assessing taxes. Hereafter, returns are compulsory and heavy penalties await the dodger. It is safe to say that at least 90% of the physicians and surgeons in Massachusetts will come within the scope of at least one of the four new taxes, and so must file returns on or before March 1, 1917.

Blanks and instruction booklets may be obtained from the Tax Commissioner's office, Income Tax Division, State House, Boston, or from the District Income Tax offices throughout the State or from any banking institution.

Broadly speaking, and with some exceptions, those forms of investments which have been tax exempt in the past continue to be so in the future, and such intangibles as have been taxed heretofore are now to be fixed at the rate of 6% of the dividend or interest yield actually received in 1916. Annuities are taxed at the rate of 1½% and the excess of actual, realized gains

over losses in the purchase and sale of intangibles is to be taxed at 3%.

Contrary to the general impression, there is no minimum exemption in these three taxes. If the taxpayer has received any income, no matter how little, from such taxable sources he must make the return.

The fourth tax is at the rate of 1½% of the excess over \$2000 of net income from profession or business. Wife, children or dependent parents may entitle the taxpayer to an exemption up to \$3000.

Partners, executors, trustees and other fiduciaries all come within the scope of the act. Although the law is necessarily as complicated as is our complex civilization, nevertheless it is believed to be as scientific and equitable as any tax law in the United States.

For his own protection it is particularly vital that the taxpayer also file with the local city or town assessors a list of his tangible personal property. This list, however, will not contain any of the items included in the return to the State as all property paying a tax on the basis of income escapes all other State or local tax. Absolute secrecy will surround the returns filed with the State, and there will be no penalty for evasions prior to January 1, 1917, but after that date the law will be strictly enforced.

As this is but a bare outline of the law, the reader is urged to obtain the instruction booklet, and make his return as soon after January 1st as may be, and, of course, not later than March 1, 1917.

JOSEPH E. PERRY,  
Income Tax Attorney.

## MASSACHUSETTS COMMISSION ON SOCIAL INSURANCE.

THE issue of the JOURNAL for December 21, which was published as a contribution to the discussion of industrial health insurance and other pending forms of social legislation, was issued two days in advance of its date in order that it might be in the hands of members of the Massachusetts Medical Society and other readers prior to the special meeting of the Council of the Massachusetts Medical Society held at the Boston Medical Library on December 20. A report of the proceedings of this meeting will be published in the next issue of the JOURNAL.

The holding of this meeting and the fact that various special committees of physicians in different parts of the state have been appointed and are actively studying the problem, are evidence that the medical profession as a whole in this state is alive to the importance of health insurance to the community as well as to physicians and is giving it careful and deserved consideration.

Meantime the Massachusetts Commission on Social Insurance has been holding meetings and public hearings since early in October, and before it have appeared many physicians and others to discuss varying aspects of the question. Before this Commission the Doten Bill, whose original text was published in full in the issue of the JOURNAL for December 7, with editorial comment, was advocated by its author, Professor Carroll W. Doten of the Massachusetts Institute of Technology. As we have previously noted editorially, however, it seems clear that this bill, as originally drafted, is unsatisfactory in its medical relations, and a new, or modified bill will presumably be drafted by the Commission and be presented before the next session of the Massachusetts General Court.

In an editorial in its issue of Wednesday, October 4, the *Boston Transcript* commented favorably on the general principle of health insurance and on the work of the Massachusetts Commission, and presented the following statistics indicating the extent of illness among industrial workers in the United States and the proportion of such illness for which adequate medical attention is not afforded:

"The latest trustworthy estimate shows that there are 13,400,000 cases of illness each year among the 33,500,000 occupied men and women in the United States and that these cases cause a total loss of 284,750,000 working days, or 8.5 days per person. To care for that part of these cases which occurs in New York City alone, there are given each year more than 4,600,000 dispensary treatments. Even so, it is carefully estimated that little more than thirty per cent. of those needing medical care apply to dispensaries. Seeking some idea of the number who may have secured private treatment, without the aid of the dispensaries, one may turn to Boston's experience. In this city the Boston Dispensary determined after an investigation of 163 doubtful cases that only 1.12 per cent. were able to pay for private care, and proceeded to the analysis that only about one-fourth of our total population was in a like financial position. So there is not only a very large percentage of sickness but also a very

large percentage of downright inability to pay for treatment of that sickness.

Summing up the situation in New York, the United Hospital Fund, speaking for forty-six hospitals, reports that

Beyond question there are large numbers who need hospital treatment but fail to apply because they do not want to become objects of charity. At present only one in ten persons seriously ill or injured in this city now gets treated in any hospital. For lack of proper treatment thousands lose their health and efficiency and become a burden to their friends and the community."

One of the leading advocates and proponents of industrial health insurance in this country has been Dr. Rupert Blue, surgeon general of the United States Public Health Service and president of the American Medical Association. He has pointed out the early origin of measures of this sort in the more progressive European countries and its steady growth until now the only countries of Europe not possessing some such form of social legislation are Portugal, Spain, Italy, Montenegro, Albania, Greece, Bulgaria and Turkey. In Sweden, France, Iceland, Switzerland and Belgium the system adopted is one of a subsidized but voluntary health insurance. In the remaining countries health insurance is compulsory. In Italy there is compulsory maternity and railroad insurance, and in France insurance is compulsory for miners and seamen. In Germany there are at present approximately nineteen million insured wage earners.

The Massachusetts Commission in its work will have the advantage of the experience of all these countries in dealing with the problems associated with industrial insurance, and its report and recommendation may be anticipated with confidence that they will present the best feasible measure of Industrial Health Insurance thus far devised.

#### HARVARD MEDICAL SCHOOL OF CHINA.

The third annual report of the Hospital Department of the Harvard Medical School of China records in full detail the work of the past year. Originally designed to afford means of clinical instruction to the students, the Hospital has proved itself a source of rich and abundant material. The students have received practical experience in history taking and phy-

sical examinations in the out-patient department and at the bedside. They have done the routine laboratory work, followed individually the progress of selected cases, have etherized and assisted at surgical operations and have seen a large number of post-mortem examinations. The out-patient department was opened to serve as a feeder for the hospital, as well as for the practical training of the students. The out-patient department has grown rapidly, and during the latter months of the past year has provided a selected clinic, rich in important and instructive cases. The well equipped Red Cross Hospital building of 47 beds is already far too small to accommodate the cases recommended for admission. Well equipped roentgen ray, pathological and surgical departments have afforded special facilities for diagnosis and treatment. A comprehensive clinical record system contains complete records of all patients admitted. A system of obtaining and reording end results has been instituted. Postmortem examinations were performed in 25% of the fatal cases from October, 1913, when the first section was performed, to June 30, 1914, in 50 per cent. in 1914-1915, and in 76 per cent. during the past year. Routine microscopic preparations have been made, and suitable material preserved as museum specimens for teaching purposes. A training school for Chinese speaking young women has been conducted for two years with promising results.

---

### HOUSEHOLD NURSING.

THERE is an important portion of every community whose need of adequate assistance in time of sickness is not satisfactorily met by the splendid organization of "trained nursing." It is a matter of expense and continuous care. The perfectly legitimate weekly charge of the graduate nurse is often as great as the weekly wage of the bread winner, and in addition he must feed and house the nurse. The district nurse may be had by the hour, but not by the week.

The family, on the other hand, are by no means fit subjects for hospital charity, and even if they were ready to accept this, beds are often not available for any but the more or less acute and short illnesses.

Some attendant must be found who is less expensive, because her training has been less prolonged and less technical, and who is more

adaptable to the simple household, because of her willingness to perform certain household duties which the responsibilities assumed by the graduate nurse make it unwise for her to undertake as a routine.

This very real and often pressing need has been fairly well met in England by the Cottage Nursing Associations, and is being supplied in this country by various similar organizations which are being formed in different cities with the help of certain funds of which Mr. Richards Bradlee is trustee. The importance of trained supervision of these attendants and of some sort of standard training of the attendants themselves is at once apparent, and in this community has been made possible through the co-operation of Mr Bradlee's organization and the Women's Municipal League of Boston.

In Jamaica Plain a Household Nursing Registry has been established, where attendants may be secured by physicians and the public. All these attendants, as a condition of their acceptance of work, accept also the supervision of a graduate nurse, who goes with them to the case, starts them on their duties, and thereafter visits them as often as the proper care of the case demands in the opinion of the attending physician, or as often as the supervising nurse's knowledge of the capabilities of this special attendant make it seem wise. This Registry has been in successful operation for over two years.

The equally great need of adequate standardized training for these attendants is being met by the Training School of the Robert Brigham Hospital, and by the recent establishment of a small Unit Training School in Lynn. Young or middle-aged women of good character and physique may obtain a two months' training under a Graduate Nurse Superintendent in the less complicated technical details of nursing and especially in the niceties of the preparation of food for the sick and the care of the sick room. The curriculum has been most carefully planned with the help of the American Hospital Association and the heads of several large training schools for nurses. At the end of two months they are placed for four months in some of the smaller but well-run hospitals, where they gain experience in the actual care of the sick. In six months, therefore, they may be employed by Household Nursing Registries under graduate nurse supervision. It is to be hoped that physicians will feel a want supplied and be glad to use these registries.

## THE HEALTH INSURANCE BILL IN PROGRESS OF IMPROVEMENT.

THE Doten bill for a state health insurance system, printed in our issue of December 7, was not regarded, by those who introduced it into the 1916 Legislature, as complete in details. This was especially recognized in relation to the medical sections. The printing of the bill should be of use to physicians in making the general scheme of health insurance clear, but physicians should not form judgment on the medical aspects of the proposed health insurance until a number of the recently drafted perfecting amendments have been considered.

There will be introduced into the 1917 Legislature a health insurance bill by the same persons who introduced the Doten bill last year, in which the medical sections have been more fully worked out, after conference with many physicians and medical organizations in this state. Further conferences are being held for this purpose. Meanwhile, the American Association for Labor Legislation has printed a greatly revised draft of the medical provisions made by its National Committee on health insurance, and these suggestions, as well as those of the Health Insurance Committee of the Massachusetts Medical Society, have been considered by the local body which has been revising the Doten bill. Continued discussion and criticism by the medical profession of the Commonwealth are desirable on this very important subject.

## MEDICAL NOTES.

CHANGES IN COST OF DRUGS.—Report from New York on December 13, records various fluctuations in the cost of certain drugs and drug compounds.

"Some of the distinctly German products which had risen to prohibitive heights owing to practical exhaustion of supplies are wavering. Permanganate of potash, which is now selling at \$2.75 and \$3 against a pre-war price of about eight cents is being watched with considerable interest. All of the potash preparations as well as a number of the fine medicinal chemicals and dye materials are in a position of status-quo so far as prices are concerned pending further developments in the European political situation.

"The principal development of interest yesterday was the announcement by domestic manufacturers of chloroform of an advance of five cents, owing to increasing demand and higher costs of production. Camphor was advanced

six cents per pound by leading domestic refiners in consequence of higher prices for crude camphor demanded by the Japanese camphor monopoly. Crushers of castor oil raised their prices one cent per pound following reports that India has declared an embargo on all future exports."

COST OF FOOT AND MOUTH EPIZOOTIC. On December 13, the United States Department of Agriculture announced the completion of its work of eradicating the epizootic of foot and mouth disease, which prevailed throughout the United States two years ago, and which necessitated the slaughter of 172,222 cattle, swine, sheep and goats valued at \$5,865,720. The cost of controlling this outbreak amounted to approximately nine million dollars, which was divided between the Federal Government and that of the several states involved.

"The disease first broke out in Niles, Mich., late in the summer of 1914, extended to twenty-two States and the District of Columbia, and was not completely controlled until last February. The true cause of the infection may never be known, but experts say it undoubtedly came from abroad.

"The expenses of eradication as paid from the Federal and States' treasuries by no means represent the full measure of the cost of this plague. The appraised valuation on a meat and dairy basis in some cases fell short of the actual value of fine pedigreed stock, but the former was all that could be allowed under the then existing law—a condition which has been remedied for the future by a provision in the latest act making appropriations for the Department of Agriculture, under which breeding and pedigree may be taken into account.

"The quarantine was gradually removed as area and States were freed from infection, and the last restrictions were rescinded June 5, 1916. For some time after removal of the quarantine veterinary inspectors were kept in the lately infected areas to supervise the restocking of farms where the disease has existed, to see whether the disease developed among animals placed on such farms, and to investigate reports of suspected new outbreaks.

"Out of the misfortune has come experience which should be of great value if the country is ever again visited by this or some other highly infectious animal plague. About 150 veterinary inspectors of the Bureau of Animal Industry, and perhaps nearly as many veterinarians in State work and private practice, took part in suppressing the outbreak and had opportunities for becoming more familiar with the nature of the disease and the best methods of dealing with it.

"Congress has seen the need of having a fund ready for such an emergency and has recently made a special appropriation of \$1,250,000 to be available for the eradication of foot-and-

mouth disease and other contagious diseases of animals in cases of emergency that may threaten the livestock industry. Some States have adopted laws and appropriated money to the same end. Perhaps the most important step needed to complete our preparation is for all the States that have not already done so to pass laws, create or improve organizations and make appropriations for dealing effectively with contagious diseases of animals."

#### EUROPEAN WAR NOTES.

**AMERICAN RED CROSS.**—The annual meeting of the American Red Cross was held in Washington, D. C., on December 13. Woodrow Wilson was re-elected president, Robert W. DeForest vice-president, Charles L. Magee secretary and William H. Taft chairman of the central committee.

John Skelton Williams presented a treasurer's report, showing the Red Cross had spent \$543,535 in the eleven months preceding Dec. 1 for war relief work, exclusive of hospital and medical supplies sent abroad. Among the relief expenditures were the following: Jewish, \$11,009; Mexican, \$44,097; Polish, \$58,938; Turkish, \$50,000, and Syrian \$8770. The balance in the treasury was reported as \$1,273,240.

Ernest P. Bicknell, director-general for civilian relief, reported that American hospital units would be withdrawn from Serbia about Jan. 1, in response to the request of the Austrian Foreign Office. He said the Red Cross had arranged to forward and distribute about \$150,000 collected for relief of Lithuanian civilians. Otto T. Bannard, of New York, member of the Red Cross commission which investigated conditions in Serbia, reported that 150,000 Serbians are destitute and near starvation. The Red Cross now has 286,461 members and 250 chapters, as compared with 22,499 members and 145 chapters a year ago."

**WAR RELIEF FUNDS.**—On Dec. 20 the totals of the principal New England relief funds for the European War reached the following amounts:

Belgian Fund .....	\$201,174.22
French Wounded Fund .....	167,740.98
Armenian Fund .....	129,688.74
French Orphanage Fund .....	72,287.36
Surgical Dressings Fund .....	59,232.17
Polish Fund .....	53,395.76
Italian Fund .....	28,558.04
Irish Fund .....	2,565.18

#### BOSTON AND NEW ENGLAND.

**WEEK'S DEATH RATE IN BOSTON.**—During the week ending Saturday noon, Dec. 16, the number of deaths reported was 201, against 255 for the same period last year, with a rate of

13.78, against 17.77 last year. There were 32 deaths under one year of age, against 43 last year, and 68 deaths over 60 years of age, against 83 last year.

The number of cases of principal reportable diseases were: diphtheria, 59; scarlet fever, 34; measles, 16; whooping cough, 6; typhoid fever, 6; tuberculosis, 41.

Included in the above were the following cases of non-residents: diphtheria, 11; scarlet fever, 7; tuberculosis, 4.

Total deaths from these diseases were: diphtheria, 3; scarlet fever, 3; whooping cough, 1; typhoid fever, 1; tuberculosis, 14.

Included in the above were the following deaths of non-residents: scarlet fever, 2.

### Correspondence.

#### THE PROBLEM OF SOCIAL HEALTH INSURANCE.

FALL RIVER, MASS., 14 December, 1916.

*Mr. Editor:*

Social health insurance is a subject that today is not only of great importance to the medical profession, but also to a large number of other people. It has for its object the taking care of persons who earn only a certain amount of wages per week or per year. The contemplated law provides for a certain amount of taxation to be assessed upon the insured, and the employer of the insured, with a contribution made by the State. The ratio is expected to be two-fifths furnished by the insured, two-fifths by the employer, and one-fifth contributed by the State. In return for the outlay upon the part of the insured, they are to receive certain benefits, namely, medical attention and medicine while sick, a certain percentage of their wages, maternity care for the wife, burial insurance, as well as appliances such as glasses, artificial limbs, etc.

The proposed law, which is a combination of socialism and despotism, is a copy of similar efforts in European countries, where it has been tried for an unsatisfactory period of time, and where it is still in an unsatisfactory state, both to the medical profession and to the people themselves. If there were no other reason than this it would be wise at least to postpone consideration of such a law until its success or failure had been established in these countries.

But this is not the only objection to such a law. There are many others. Were it possible to work this plan out to the satisfaction of all concerned, there is no question that it would be an ideal condition, but the difficulties of the problem are so great that it is inconceivable that it would ever be satisfactory to anyone, especially in the feature that calls for medical attendance. In order to carry it through, the tax upon the insured would necessarily be small. It would naturally follow that the compensation for medical aid would also be meagre. As the law would permit a large majority of the people in most of our Massachusetts cities to insure under the act, it would follow that the panel system, which would be inaugurated, would compel doctors, if they would make a living by it, to take a large number of people to care for. The amount of work they would do would be great; the compensation would be small. There would be neither inducement nor opportunity for the performance of the best medical work. Medical men, after all, are only human, and unsatisfactory conditions, such as overwork and underpay,

would be no more alluring to them than to other men. It would be inconsistent to believe that because men are practising medicine they could possibly be satisfied with conditions so entirely unfair. From the sure lack of time, as well as the lack of a stimulus to personal ambition, it would follow that the work would be carelessly done. While carelessness on the part of the medical profession is inexcusable, yet that charge is made over and over again against the panel physicians in England. It is hardly to be expected that any better results would follow the working of the act in this country. The conditions simply breed carelessness, and while that might not be a universal fault, it would certainly be a common and grave fault, which in the end would work serious harm to the people insured. It would, therefore, be unfortunate legislation for the proposed beneficiaries, who would win only a false security.

What, now, would be the advantages to the medical profession from such an act? None whatever. The English plan for carrying out the provisions of the law is through either a per capita assessment, or one where so much per call is paid the physician. The per capita assessment plan is the most dangerous, in being likely to foster all the possible abuses of such a system. The per visit plan, while being fairest to the physician, could not reasonably be expected to succeed. In order to pay a satisfactory fee, it would burden the project with an expense which would make the tax so great that the people would be unwilling to pay it. There is slight possibility that the per visit plan would ever be adopted. The expense makes it inadvisable and impracticable. Either plan would mean a great loss in revenue to the medical profession,—a loss which the profession is not able to stand. The fees paid European physicians, or even much larger fees, would not support American physicians. It would not only work injustice to the men in the profession at present, but, considering the amount of time and money that medical education costs, with the probability of greater expense in the near future, it would appear improbable to man the profession in sufficient numbers to care for the sick. The practice of medicine must necessarily, to most men, hold out an opportunity for making a living, and surely no one could conceive of this act furnishing a means of livelihood. We are, therefore, called upon to face a grave crisis, wherein the future of the profession, as well as our own livelihood, is at stake.

The danger is great, and comes from many directions. Not only do well-meaning sociologists, and self-advancing politicians see in this measure attractive possibilities, but we should have many in our own profession who, through affiliations or associations, or who, perhaps, because of their position, would be indifferent, believing that they themselves would not be touched by this law. If we are to safeguard the best interests of our profession, we cannot too soon prepare to meet this issue. United action on the part of the profession, or the greater part of the profession, will control the situation. It will secure either reasonable compensation or, better still, defeat the medical part of the social health insurance proposition. If this act promises no benefit either to the insured or to the physicians; if it threatens the life and health of the insured, and the livelihood of the physician, as well as the future of the medical profession, it is difficult to see any excuse for enacting it into law. Granting that theoretically it appears satisfactory, practically it secures nothing in a medical way that the people do not now possess. Our physicians and our hospitals are constantly taking care of a large number of sick persons who are not able to pay for the services rendered. The medical profession prefers to do it in this way. No injustice is being done to the people at large, under the present system. Every sick person can be taken care of properly.

THOMAS F. GUNNING.

## THE AMERICAN AMBULANCE HOSPITAL.

(From our Special Foreign Correspondent.)

PARIS, November 10th, 1916.

Mr. Editor:

Perhaps your readers may like a word regarding the activities of the American Ambulance Hospital at Neuilly during the past summer. The hospital itself is so favorably known, both to the profession and to the laity, that but little need be said regarding its excellence. Nevertheless, the writer cannot refrain from expressing the feeling of surprise and admiration which he had on arriving here for duty, May 1. The hospital seems hardly to be a temporary one, so well arranged and convenient are its various wards, its operating rooms, offices and other departments. Indeed, it has been facetiously said that when the architect designed high school buildings, he unwittingly succeeded in planning a modern hospital!

The work at the Ambulance during the last six months has been exceedingly active. In the early part of the summer the cases came largely from Verdun, while since the beginning of the Somme offensive almost all of the wounded have come from that region. These Somme cases arrive on an average from two days to five days after injury, thereby reaching the hospital earlier than did the patients from other portions of the front.

The very great majority of the cases admitted have been of a grave nature, as has been the case since the beginning of the war. Severe shell injuries of the long bones and joints; chest, neck and head injuries, and especially the extensive loss of facial tissues (soft parts and bone). The hospital has continued to be a centre for these so-called face and jaw wounds, and through the fortunate cooperation between the dental department and the general surgeons, exceptional results are obtained in these sadly disfiguring cases.

The surgery of the peripheral nerves occupies a large part of the attention of Dr. J. P. Hutchinson, the surgeon in charge of Service B. Dr. Hutchinson has already operated on some fifty cases of nerve injury, and something like one hundred more cases are at the Ambulance proper, or in auxiliary hospitals, awaiting a suitable time for operation. Naturally, it is too early to speak of results, but the material thus accumulated will furnish valuable statistics when studied later.

Very much might be written in detail, but it may suffice at this time to say that the hospital is looked upon with much favor by the French Government, and that it continues to endeavor to maintain the best traditions of American surgery.

CHARLES A. POWERS, M.D.

## INDUSTRIAL HEALTH INSURANCE.

Boston, December 15, 1916.

Mr. Editor:

I have just read the draft of provisions of the Committee of the Massachusetts Medical Society, as published in your Journal, December 14, 1916. It is a tentative one, inviting discussion. On the whole I agree with my idea of health insurance or, to be more polite, I agree with it. In defense of a previous article, I must, however, disagree with some of its details. Please do not consider me hypercritical on that account. I am merely performing what I consider a duty at this critical time.

In Section 1 of the proposed change, I read, "Competent physicians and surgeons shall name those upon the panel, as provided for in Section 2." My first objection to this sentence is, that the implication is too broad, that those not on the panel are incompetent. My second, that the word "panel" is an accident of the British and German Acts, and a bad accident at that. It should not be perpetuated. There is nothing in the principle of health insurance which demands it. Let us forget it and the panel system

2. In Section 2, provision is made, that every physician wishing to serve under this act, shall, before a certain date, register with the Commission. This provision is a duplication of effort, and unnecessary, as all physicians are already registered in the Commonwealth.

Again, in this section, I object to the restriction which limits a practice to 500 families or 2000 individuals. It is unconstitutional. Much as I should desire such a large practice, I object to the principle. Imagine telling a large mercantile firm that it could sell only to 2000 purchasers. This idea is another foreign inheritance, that should not be allowed to take root in the "land of the free."

3. Section 3. Appointment of physicians and surgeons as referees. Theoretically sound. Practically, too much one-man power. Caesar's wife the only candidate qualified by training and experience for the position. This section needs further revision.

4. Section 6. Hospital Treatment. This brings up the question which was one of the immediate causes of the foundation of the American College of Surgeons. And, again, we are confronted with fact, and not theory. If this proposed legislation does nothing more than to bring this matter to a head, it will have done much. As a matter of theory, we all know what a hospital should be. There is a crying need for hospital legislation which shall transform theory into fact. As a matter of fact, however, we are face to face with a condition. The civil authorities have licensed many to operate hospitals. Ours not to reason "why." Compulsory contracts would operate against some. They are, therefore, unconstitutional. We must not remedy one evil by creating another.

Yours fraternally,

JOHN J. HURLEY, M.D., F.A.C.S.

#### A PHYSICIAN'S DISCLAIMER.

Boston, 7 December, 1916.

We have recently received from Dr. S. Adolphus Knopf, Professor of Physiotherapy at the Post Graduate Medical School Hospital of New York City, a letter disclaiming personal responsibility for an advertisement which appeared on page 66 of the *Journal of the American Medical Association* for November 4, 1916, in which it was stated that Dr. Knopf had patented a certain window tent of his invention. Dr. Knopf denies categorically that he was concerned in the patenting of this tent, which, he states, was done by others without his knowledge. It seems only fair to Dr. Knopf that his disclaimer should be published in this form, that readers of the *JOURNAL* may have the opportunity to know his attitude and position in the matter.

EDITOR.

#### A CORRECTION.

Boston, December 10, 1916.

Mr. Editor:

My attention has been called to an editorial in the *JOURNAL* for November 20, which speaks of me as Dean of Tufts College Medical School. As is well known in medical circles, Dr. Charles F. Painter is Dean.

Yours very truly,

FRANK G. WHEATLEY, M.D.

#### NOTICE.

Members of the medical profession are cordially invited to participate in the presentation by the dental profession of a loving cup to Mr. Thomas Alexander Forsyth, the founder of the Forsyth Dental Infirmary for Children, at a banquet to be held Jan-

uary 20, at half after 6 o'clock, at the Hotel Somerset, Boston.

Tickets for this banquet (subscription, \$5.00) can be obtained from any member of the committee. Checks should be made payable to Dr. Charles Smith, 35 Butler Exchange, Providence, R. I.

FREDERICK A. KEYES, D.M.D., *Chairman*,  
PERCY R. HOWE, D.M.D.,  
F. S. BELYEA, D.M.D.,

*Banquet Committee on Publicity.*

#### SOCIETY NOTICE.

NEW ENGLAND PEDIATRIC SOCIETY.—The forty-fifth meeting of the New England Pediatric Society will be held in the Boston Medical Library, Friday, Dec. 29, at 8.15 p.m.

I. Report of Council and nomination of officers.  
II. The following papers will be read: 1. Case Report, Wyman Whittemore, M.D., Boston; 2. "Some Observations with Sour Milk Feeding," C. K. Johnson, M.D., Burlington, Vt.; 3. "Difficulties in the Diagnosis of Diseases of the Hip-joint," A. T. Legg, M.D., Boston; 4. "Should All Milk be Pasteurized?" Richard S. Eustis, M.D., Boston.

III. Election of officers.

Light refreshments will be served after the meeting.

A. C. EASTMAN, M.D., *President*,  
RICHARD M. SMITH, M.D., *Secretary*.

#### RECENT DEATHS.

DR. ROBERT BRINE HARRINGTON, who died recently at Grand Junction, Colorado, was born on July 30, 1879, in Somerville, Mass. He received the degree of M.D. from Tufts Medical School in 1904, served for a year as resident at the Tewksbury State Hospital, and in 1906 settled in Colorado, where he became county and city physician at Grand Junction. He is survived by his widow and two daughters.

DR. CHARLES BUTLEY, who died of cerebral hemorrhage on December 15 at Waverly, Mass., was born at Lewiston, Maine, in 1854. He received the degree of M.D. from Bowdoin and, for a time, practised his profession in Saco, Maine. Later he removed to Malden, Mass., but retired from general practice about 1900. He is survived by his widow and two children.

DR. GEORGE EMMONS SAVAGE, who died on December 14, at Leicester, Mass., was born in Rutland, Mass., on January 5, 1851. He studied dentistry with Dr. Sumner C. Whitney of Worcester, and in 1884 began the practice of his profession in that city. He was a member of the Northeastern Dental Association, of the National Dental Association and of the Massachusetts Dental Society, which he served as president in 1907. In 1908 he was chairman of the section on clinics of the National Dental Association, and was a delegate to the Fourth and Fifth International Dental Congresses, of which the latter met at Berlin in 1909. He is survived by his widow.

DR. WALTER JAMES DODD, a Fellow of the Massachusetts Medical Society, died at his home in Boston, December 18, aged 46 years. He was a native of England, became apothecary to the Massachusetts General Hospital in 1896, and photographer as well, graduated in medicine at the University of Vermont in 1908, and since then has been roentgenologist to the same hospital. For 16 years he had suffered cheerfully with x-ray burns and cancerous sequelae, and he succumbed finally to one of many operations performed for the removal of affected glands. He is survived by his widow, who was Margaret Lea of Moncton, N. S.
